Although this report of the Physical Activities Survey bears the sole authorship of the undersigned, whatever success the survey may have achieved is due mainly to the contributions in time and/or thought of these individuals and organizations:

The Department of Civil Service, State of New Jersey and the New Jersey State Law Enforcement Planning Agency for supplying the necessary funding.

Wayne Boyd, Director of Examinations and his colleagues, in the Department of Civil Service, William Parikas, Robert Maurer and Thomas Johnson for providing appropriate support, criticisms, and suggestions for improving the study.

Leo Culloo, Leonard Harrison, and Robert Walsh of the
New Jersey Police Training Commission for reviewing the
questionnaire and for suggesting improved methods of administration.

Mike Prisco and his brother officers of the Lakewood Police Department for their invaluable assistance in the field trial of the PAS questionnaire.

Samuel Barnett, my colleague at ETS, for giving me the benefit of his experiences as a police officer, a researcher, and a human being.

Linda Staples, who helped with the distribution and coding of the questionnaires. Rob Patrick, who directed the processing of
the data from purching through computer print-out. Pat Fisher, for her secretarial skills and beaming visage.

Finally, the deepest appreciation and gratitude is expressed to the chiefs and their men who contributed the information on which the study is baser. Hopefully, their contribution will serve to benefit their brother officers.

None of the above bear responsibility for any errors of omission or commission which may have found their way into this report. Such responsibility is that of

## PHYSICAL ACTIVITIES SURVEY

## Introduction

The police officer's job has changed greatly over the last three decades. Much of this change is a reflection of changes in society generally which have come about since the era of World War II.

Increases in population, tremendous scientific advances, "minority" pressures for equality in education and employment, for example, have necessarily had their effect on the police profession. Even considering the police officer's job as a profession is a fairly recent innovation

Because of these, and other changes, today's police officer is subject to a variety of dangers and pressures not previously present. The generally sedentary nature of police activities coupled with irregularly occurring demands for instantaneous physical acuity and exertion make it imperative that police officers be in excellent physical condition not only upon entering the profession but particularly through their later years on the force. Many police officers can relate at least one instance in which a brother officer, confronted with the need for sudden physical demand succumbed to failure of either heart or central nervous system.

The State of New Jersey Department of Civil Service and the State Law Enforcement Planning Agency, cognizant of the physical demands of the police officer's role, authorized ETS to conduct a survey of police officer's physical activities in jurisdictions within the state. The prime objective of this survey was to collect
information about the kinds of physical activities police officers perform, their present health status, what measures they take to maintain good physical condition and their appraisal of the present civil service physical performance test battery. Another aspect of the study was to examine the relation between and among these measures and the effects of other factors such as age, experience, rank, and type of assignment on present health status. This information would be used to assist the Department in an evaluation of the efficacy of the constituent parts of the present physical performance test, to uncover any significant relations between job requirements and the maintenance of good health, and to signal the need for specific action that the Department, SLEPA, or other state or local agencies might take in order to assist police officers in maintaining good physical condition.

## Development of the Physical Activities Survey Questionnaire

In order to accomplish the stated objective a Physical Activities Survey questionnaire was developed to elicit information about the name of the community in which the respondent worked, his rank, duty assignment, length of experience, age, height, weight and the percent of time spent during an "average" day in each of 18 activities covering a broad range of physical actions police officers might perform. On the basis of critiques received from Department of Civil Service personnel and members of the Police Training Commission, the questionnaire was completely revised in order to accomplish a much broader investigation.

Rather than having respondents react to a predetermined list of physical activities, the revised questionnaire asks the respondent to name those physical activities most often required by his job. In addition to the background information requested on the earlier form, the later version collects information about weight change since appointment, a self-estimate of present physical condition, recency of physical examination, changes in visual and auditory acuity since appointment, medical complaints or conditions developed, type and regularity of exercise, importance of physical condition to the job, ava'lability of a physical fitness prograni in the jurisdiction, attitude toward each part of the civil. service physical performance test (whether to keep, eliminate or change it) and whether the respondent could pass each part if he were tested now. Ihis second form of the questionnaire was submitted to Civil Service and Police Training Commission personnel for review. Some relatively minor, but nevertheless helpful, changes were suggested and incorporated into the final version. In order to detect any unioreseen or undiscovered difficulties with the questionnaire or the directions for its administration, a field test was conducted wilth ten members of the Lakewood Police Department. This trial went smoothly; there was no apparent need for additional changes. The Physical Activities Survey (PAS) questionnaire was then distributed to police officers within New Jersey, in accordance with the research design.

## Design of the Survey

The frequency and severity of the kinds of demands made on police officers may be related to and/or affected by the community in which the police officer performs his duty. Therefore, a broad sampling was made of police jurisdictions within the state. Initially, communities within each of the 21 counties were selected from an alphabetical listing of police departments which indicated the total number of men in each department as well as the number at each rank from patrolman to chief.* Within each county, the largest community and the smallest (with at least 10 men ) were identified. Of the remainder, every third or fourth community was chosen for inclusion in the survey. In this manner, 108 jurisdictions were selected for the first contact.

A number of PAS questionnaires equal to approximately $25-30$ percent of the men in the jurisdiction were addressed and mailed to the Chief of Police of each selected department. Accompanying each mailing was a letter from the Director of Examinations, Department of Civil Service, to the Chiefs of Police, describing the intent of the survey and requesting their cooperation. In addition, a letter from the project director and directions for admiristration of the questionnaires were included. (See Appendix for copies of these documents). The requested date for returning the completed questionnaires was approximately 10 days after the estimated time of their receipt at the designated police headquarters.

[^0]Inadvertently, questionnaires were sent to communities which do not utilize civil service procedures for selecting their police officers. Thiryy-nine of the first 108 communities contacted are In this category. In order to compensate for the reduction in sample size, another selection was made from a roster of civil service comunities.

Since relatively few departments (with ten or more men) then remained unsampled, it was decided to include them in the study. Thus, the police departments of 132 communities which select their police officers through the state civil service were contacted as potential participants in this survey.

## Representativeness of the sample

Since questions pertaining to the civil service physical performance tests are an integral part of the questionnaire and the respondents' attitudes toward these tests are of paramount interest to the sponsors of the survey, questionnaires returned from non-civil service jurisdictions were not included in the study. Although a comparative study was suggested, the small size (approximately 150) of the non-civil service sample makes this impracticable.

Of the 187 civil serivce jurisdictions, questionnaires were sent to 132. Completed PAS questionnaires were received from 92 of these jurisdictions in time for inclusion in the study. Returns from two communities arrived too late to be processed. Therefore, seventy percent of the civil service police departments contacted supplied the data for this survey.

One of the first questions which must be asked of a survey of this type is "How representative of the population being studied is the sample of completed returns?" The key word here, of course, is "representative".

Jurisdictions from 17 of the state's 21 counties are represented in the sample. Two of the counties not represented (Somerset and Hunterdoti) have no jurisdictions which use civil service procedures for the selection of their police officers. Only Atlantic and Salen counties are unrepresented because none of their civil service jurisdictions elected to participate in the survey. On this gross county level, the sample is representative.

A report, prepared by the Police Training Commission referred to earlier, lists the number of men at each rank from patrolman to chief in the organized police departments in the state as of April, 1968. This personnel breakdown or "census" provides a base for comparison for the PAS sample. For the 17 counties represented in the PAS, the "fit" between the 1968 census data and the PAS sample is quite close (Table 1). The largest deviation, that for Essex county, is less than $6 \%$. The "overrepresentation" of Mercer and Union counties is less than $3 \%$ in each case.

In addition to representativeness by county, we can examine representativeness by rank. The number and percent of men at each rank from patrolman to chief, for the 1968 data and for the PAS sample, are given in Table 2. Here, the differences in percent at each rank are relatively small. The largest, an "underrepresentation"
of patrolmen, is only $3.5 \%$. The "overrepresentation" of sergeants and detectives is less than $2.5 \%$ in each case. If, for each rank, the ratio of men in the PAS sample to the number in the 1968 data is considered, we note that between 12 and 20 percent of each rank except Inspector and Chief is represented in the PAS sample, Since, however, the number of chiefs is directly related to the number of departments, the 13 chiefs represent almost 15 percent of the jurisdictions sampled.

The distribution of men across assignments is given in Table 3. Although no comparative figures are available it is assumed that the large proportion of men assigned to patrol duties is not unrepresentative of general statewide conditions.

In general, the PAS sample of 1875 police officers in 92 departments located in 17 counties of New Jersey reflects fairly closely the county and rank distributions of the population of police officers in the state. Generalization of the findings of the PAS is defensible.

## Results

1. Characteristics of police officers related to community size.

The PAS sample was classified into four categories of community size. The number and percent of sample questionnaires in each category within each of the 17 counties is shown in Table 4.

Six percent of the total sample comes from police departments in communities of fewer than ten thousand persons. The greater portion of these returns come from Bergen, Burlington, Cape May,

Monmouth and Ocean counties. More than 28 percent of the sample comes from communities of ten to thirty thousand. Bergen, Burlington, Morris and Union counties provide the majority. Most of the returns from communities in the thirty to fifty thousand category, which accounts for almost 27 percent of the total, come from Bergen, Essex, Hudson, Middlesex and Union. The largest category, 39.1 percent of the sample, is from communities with more than fifty thousand people. Police jurisdictions in Essex, Hudson, Mercer, Passaic and Union supply more than 80 percent of these completed questionnaires.

Is there a relationship between the size of the community and certain characteristics of its police officers such as years of experience, age, height, and weight? Analysis of the data of Table 5 and Table 6 reveals a significant difference in both the experience and age of police officers between communities of different size. In both cases there is a straight line trend; the men in departments in larger communities, on the average, have more years of service and are older than police officers in less populated jurisdictions. Although similar differences hold across rank, i.e., men in higher ranks are, on the average, older and more experienced than men in lower ranks, significant differences do not exist, within rank, between communities of different sizes.

Exploring the possible influence of community size on the height and weight characteristics of its police force, Table 7 indicates no such effect. As would be expected, taller police officers generally
are heavier than their shorter peers. However, there is no evidence to indicate significant differences in weight between men serving in communities of different size, either across or within height.

A1though the inter-community differences in experience and age are statistically significant, the magnitude of the largest difference (between the smallest and largest communities) is less than three-and-a-half years. For subsequent analyses, the data are pooled across communities; no differentiations are made on the basis of community size.
2. Physical characteristics and health status of the respondents

The typical New Jersey police officer, as defined by the PAS sample, is approximately 37.5 years old, stands just under 5'11", weighs almost 189 pounds and has been on the job for 11.5 years (Tables 8 through 11). He has gained more than 14 pounds since appointment (Table 12). If asked to describe his present physical condition, he would most likely answer "good" (Table 13). He probably did not wear glasses when he was appointed. Chances are still about two-to-one that he doesn't use glasses for reading and about nine-to-one that he doesn't need them for driving (Tables 14, 15, 16). In all likelihood, his hearing hasn't become impaired (Table 17). Although men fitting this description may actually exist, this "typical" police officer is only a statistical concoction. (See Document A in Appendix)

Of more immediate concern, however, is the health status of New Jersey's police officers as reflected by the PAS sample.

By self-report, $88.8 \%$ of the respondents claim to be in good or excellent health (Table 13). Nevertheless, more than half the group, (57\%) which checked those physical symptoms or diseases they had developed since appointment checked at least one (Table 18). More than a quarter of the group (28.6\%) checked two or more complaints. An examination of these specific conditions (Table 19) shows back trouble, loss of teeth, and hemorrhoids to be those most frequently mentioned. A not inconsequential percent of the group lists high blood pressure, ulcer, and nervous disorder, while more than ten percent indicate other unclassitied physical problems. A closer investigation of how these complaints relate to other characteristics of the police officer and his job is made later in this report.

How important is good physical condition for the effective performance of the police officer's job? Sixty-nine percent of those replying to this question said that it is very important (Table 20). This at titude is probably reflected in the data of Table 21 which show that more than 63 percent of the respondents do some exercise regularly each week. Table 22 , in addition, shows that those who feel most strongly about the importance of physical condition are also those nost likely to engage in some regular exercise. Calisthenics is the most popular exercise, although 36.5 percent perform some exercise other than those listed (Table 23).

## 3. Physical activities required by the job

The sedentary nature of the police officer's job is evidenced by the data of Table 24. Sitting is identified by more than three-
fourths the group as the physical activity required most on the job. Walking is named by over half the group, standing by almost six percent, and driving by five percent. Of those activities requiring somewhat more exertion, running is most frequently mentioned (11.7\%). Wrestling (some form of body contact), lifting and climbing evoke a response from less than three percent of the group. We will return later to a fuller examination of how these physical activities on the job relate to other personal and occupational aspects.
4. Evaluation of the physical performance test battery.

Thus far, we have made an overview of the kinds of physical activities police officers perform, their present health status, and the measures they take to maintain good physical condition. Let us now explore the PAS sample's appraisal of the six tests of the civil service physical performance battery (Table 25).

The 100 -yard agility test is the most popular. Nine out of ten officers responding elect to keep it in the battery as it is without change. In contradistinction, less than three-fourths of the group would keep the squat jump; $16.1 \%$ would eliminate it completely. The remaining tests are accepted, as is, by about eighty percent of the group, although chinning and broad jump would be eliminated by more than ten percent.

Which parts of the physical performance :est battery do the respondents think they could pass if they were to be tested today? The differential responses are supplied in Table 26 which shows that the largest percentage of the group feels that it could pass
the sit ups test ( $82.8 \%$ ) while the squat jump would be passed by only $69.1 \%$.

How is the officer's confidence about passing the test related to his attitude about keeping it in the battery, eliminating it or changing it? This question is answered by the data of Table 27. For each test, the relation between ability to pass the test and attitude toward its retention in the battery is highly significant. Generally, those officers who feel they could pass the test are more strongly in favor of keeping it as it is; those who feel they couldn't psss are more strongly in favor of eliminating the test.
5. Factors related to physical activities required by the job.

It was noted earlier (Tab1e 24) that sitting, walking, and running are the physical activities mentioned most frequently by the respondents as being required on the job. In this section, the relation between these activities and other personal and occupational factors is examined more closely.

If we discount the ranks above captain, because of the relatively small numbers represented in the sample, we note the increased tendency for "sitting" to be reported as a required activity as rank increases (Table 28). This probably is a reflection of the increase in aüministrative duties with rank. Walking appears to be an activity more related to the work of detectives than men of other ranks.

Those engaged in administrative duties do proportionately more sitting than men with other assignments (Table 29). This corroborates the findings of Table 28 mentioned above. Men assigned to narcotics
divisions report the least amount of sitting and the greatest amount of running. Training, traffic, and records people do the most standing, while those in juvenile work and traffic report the greatest incidence of driving on the job. Presumably, these findings reflect directly the nature of work done by men assigned to the different divisions.

The relation of experience to physical activities (Table 30) is almost identical with that of age to physical activities (Table 31). Older and more experienced officers tend to spend a greater proportion of time sitting than do younger, less experienced men. Conversely, running as part of the job is reported more frequently by the less experienced, younger police officers; it decreases as a reported activity directly with an increase in age and experience.

A change in an individual's weight may be regarded as an index of both aging and health status. Table 32 shows that men with the greatest gain in weight since appointment report the greatest percent of sitting and the least of running. Those men with extreme weight losses also report a high proportion of sitting but they walk and run more than do the men who have gained more than 30 pounds.

Is there some relation between the kinds of activities an officer performs on the job and the symptoms or diseases he claims to have? The answer to this question is contained in the findings of Table 33 which indicate that the relationship, if one exists, is not very strong. A note of explanation about the interpretation of this table is needed before proceeding.

The percents shown are for the men who report specific activity and the presence of a specific disease or symptom, i.e., "yes" to both the activity and the disease. What is not indicated is the percent of men who claim the activity but not the disease or the percent who claim the disease but not the activity, i.e., the "yes-no" and "no-yes" cases. Therefore, although a percent reported in the table may be higher than another, for a specific disease, it may not be statistically significant while a smaller percent entry is. For the 1334 men who report "sitting" as a required activity, a significantly high percent report having hemorrhoids. The incidence of varicose veins for this group is significantly less than would be expected. The percent of cases of hemorrhoids reported by the men who walk on the job is also lower than chance expectation. Those police officers who report running as a job requirement also report less-than-chance percents of back trouble and loss of teeth. This may be an indication chat those men who are required to walk or to run on the job may be in better health than those who are less active. This contention seems warranted on the basis of the entries in the "None" column. A significantly small percent of those who sit on the job claim to have no diseases. However, the proportion of those who walk or run on the job and who claim no symptoms or diseases is signiricantly greater than expected.

## 6. Factors related to present health status.

The PAS questionnaire provides two indices of present health status; the self-report of present physical condition and the symptoms or diseases claimed by the respondent. We look first at some factors which may be related to the self-report of present physical condition.

From Table 34, we note that reported health status appears to vary inversely with age, i.e., those officers reporting themselves in excellent health are, on the average, younger than those claiming good, fair, or poor health. Average age increases as reported health status worsens. This general age effect is also apparent in Table 35. As years of experience as a police officer increase, the percent reporting excellent or good health decreases.

The relation of rank to reported health status, Table 36 , tends to parallel that of age and experience, although the small number of respondents at the higher ranks makes this evaluation somewhat equivocal. The disparity in the number of respondents in the various assignment categories also makes the interpretation of the data of Table 37 somewhat difficult. However, those assigned to the Narcotics division and those in Training do report the largest percent of respondents in excellent or good health; those in Communications and Records and Identification report the largest percents of fair and poor health status.

The effect of extreme weight gain on reported physical condition is reflected in Table 38. More than $20 \%$ of those gaining more than

30 pounds since appointment consider themselves to be in fair or poor health.

The presence of diseases or symptoms, too, apparently influences the individual's estimate of his health status. Compared with those who state that they have no symptoms or diseases, those respondents claiming at least one disease report relatively higher incidences of fair or poor health (Table 39). This is particularly true for those claiming lung disease, heart disease, varicose veins, high blood pressure, or nervous disorder.

The police officer's evaluation of his present physical condition is directly related to the confidence he expresses in his ability to pass the civil service physical performance tests (Table 40). In each case, the relation is clear and strong; the higher the estimate of personal health status the greater the confidence in one's ability to perform successfully.

As proposed above, the presence of disease or symptoms is another index of the officer's health status. An indication of the effect of age on the reported presence of disease is clearly evident in Tables 41 and 42. All the diseases and symptoms investigated, except flat feet and lung disease, show a significant increase in incidence beginning sometime in the fourth decade of life. Less than forty percent of respondents in each of the age categories above 30-34 report complete absence of disease or symptoms, compared with incidences (of no disease) above $50 \%$ for those in the younger age categories.

This finding is reproduced almost identically in the effect of experience. Incidence increases dramatically after approximately 10-14 years as a police officer for all diseases, with the two exceptions noted earlier. This length of experience is achieved usually by age thirty to thirty-five. The relatively high incidences of heart disease and high blood pressure for men of 45 and older as for those with 20 or more years experience, should be noted. Back trouble, in particular, and hemorrhoids should also be cited because of their inordinately high frequency of occurrence. These data may signal the need for police jurisdictions, on the local or state level, to take some preventive or ameliorative actions in regard to these conditions which may endanger the police officer's life or cause him much discomfort.

The relation of presence of disease to raxk, Table 43, is not as clear. There is a tendency for men at the ranks of sergeant and higher to report a higher percent of complaint. Loss of teeth, ulcer, and other unclassified conditions are of significance here. (The data for flat feet, although statistically si.gnificant, should be viewed with suspicion because of the extramely low incidence of the condition and because of the low number of respondents in the ranks above captain.) Hemorrhoids, back trouble and high blood pressure tend to be reported more frequently by men at the sergeant's rank or higher.

Heart disease, hernia, and the lack of disease seem to be associated with a man's assignment (Table 44). To a lesser extent, this appears to be so also for the complaint "loss of teeth."

The highest percents of incidence of heart disease are reported by men in unclassified assignments, traffic, communications, records and identification, and detective divisions. Hernia occurs most frequently among men in communications, detective division, and other unclassified assignments. Proportionately, the highest incidence of the presence of at least one disease or symptom is reported by men in communications work. Administrators, traffic, records and identification, detective, and juvenile assigned personnel report incidences of more than $60 \%$.

Table 45 examines the association of extreme weight changes with the reported presence of disease. Perhaps not unexpectedly, back trouble and high blood pressure can be singled out as being significantly related to extreme gains, i.e., twenty or more pounds. This is true too for hemorrhoids, loss of teeth, and ulcer (at a lower level of statistical significance.) These data suggest that the significantly higher percents of older and more experienced officers reporting back trouble and high blood pressure might be associated with increased weight. Further investigation of this point might indicate the need for preventive measures such as more carefully regulated diet and regular exercise schedules.

There is some evidence, Table 46, that performing some form of exercise regularly is associated with a lower reported incidence of disease. Lung disease, loss of teeth, and ulcer are conditions reported significantly more frequently be respondents who engage in no regular exercise than by those who do some exercise either regularly or irregularly.

Calisthenics, the most popular form of exercise, is practiced by a greater proportion of younger men (those under 35). Swimming is preferred to a greater degree by men over 40 years of age. Lifting weights and jogging tend to be performed more by younger men although the age differentiation is not as pronounced as with calisthenics (Table 47).

Among the men who report some form of exercise on a regular or irregular basis, Table 48, there appears to be an underlying age relationship. A greater proportion of men over 40 exercise irregularly while younger men, in the main, exercise regularly one to three times per week.
7. Other indices of health awareness.

By far, the largést portion of those reporting, almost $73 \%$, have had a doctor's examination within the past year; more than half of these within the last six months (Table 49). A relatively small number, less than $12 \%$, had their last physical examination by a doctor more than two years ago. These data indicate a positive attitude toward the maintenance of good health.

Another aspect of this general attitude is evident in Table 50. Almost $80 \%$ of the respondents representing jurisdictions without physical fitness programs express the view that such programs should be made available. Using as a benchmark the percent of participation in communities which do provide fitness programs, Table 51, we would estimate that more than half this group would avail itself of the opportunity to maintain good physical condition if a program were made available.

## Discusision

The responses to the Physical Activities Survey questionnaire of 1875 police officers employed in 92 municipalities of 17 of New Jersey's 21 counties were analyzed; the findings have been presented in the preceding sections. Attention has been focused primarily on the kinds of activities police officers perform on the job and how these are related to other occupational and health factors. We have also been concerned with the present health status of these men and how it is associated with job characteris+ics. An evaluation of the respondents' attitudes toward the civil service physical performance tests has also been presented.

A study such as this would be remiss if it merely presented its findings without interpreting the results or without attempting, however feebly, to draw conclusions on which future actions might be based. In order not to be derelict in this regard, the following interpretations and suggestions are offered.

In comparison with many other occupations, that of police officer is staffed by selected individuals who are required to meet and comply with fairly exacting intellectual, physical, and psychiatric standards. However, particularly in the physical domain, time and the nature of the police officer's job soon appear to have deleterious effects. Within ten to fifteen years after first donning the uniform, police officers begin to increase sharply the frequency of their physical complaints. This upward trend continues over time.

A substantial portion of this diminishing health status appears age-related but much of it may also be due to the largely sedentary
features of the job. We have evidence that this decline is somewhat less severe for those who are more active either on the job or because of a self-imposed routine of physical exercise. Extreme increases in weight also seem to be implicated in physical deterioration. Therefore, some remedies or suggestions for the maintenance of good physical health are almost self-evident.

Some form of regular exercise combined with a program of weight control might be quite effective in maintaining or improving physical condition thereby reducing the incidence of complaints. The implementation of such programs at the local level probably should include some preliminary diagnostic work-ups in order to identify those men who are most in need. For these, the program should be mandatory and should provide for periodic examination or evaluation to determine its effectiveness. For those men who are in good physical condition, the program would be voluntary until a change in condition necessitated making it mandatory. Since four out of five respondents indicated their receptiveness to the idea of a physical fitness program, putting a program such as that outlined above into effect statewide might be accomplished, with federal and/or state assistance in funding and planning.

The New Jersey Police Training Commission has recently recommended that a mandated physical training program be introduced in the police academies in order to help trainees "improve the general muscle tone and sharpen the mental process, . . . . prepare for participation in Defensive Tactics, First Aid, Firearms Training and other activities of a physical nature, . . . . (and) through teaching proper lifting
techniques and giving exercises aimed at strenghtening seldom used back and stomach muscles to reduce the incidence of occupational hazards such as 'bad backs', hernias, muscle strains or tears, etc."1 The trainee soon develops into the experienced veteran who, in the absence of appropriate maintenance measures, will fall prey to the rigors of ageing and the job. Why not then see to it that a program of this type is made available to the men after they have completed academy training?

The large proportion of complaints of "back trouble" and "hemorrhoids" might well be related to the high incidence of sitting, either on a chair or in a patrol car. Here, several possibilities suggest themselves. The simplest one might be getting off the chair or the car seat periodically and just bending or stretching or walking around. As a second resort, the ingenuity of orthopedic specialists and engineers might be enlisted to design more comfortable and more efficient seats. Where feasible, rotation of assignments might be made periodically so there is alternation between sedentary and more active roles.

According to our data, heart disease and high blood pressure tend to increase rather sharply after the age of 45. A program of exercise and weight control might have some positive effect here. Another preventive measure, however, woult be the instituting of an annual physical examination by a physician for all men over 45 and

[^1]somewhat less frequently for younger officers. Again, there is a cost factor to be considered but, certainly, sources of funding should be explored.

Going off on a different tangent, let us consider some possible suggestions regarding the civil service physical performance tests. One overriding question is: "Should the present battery of six tests be retained?" Although more than seventy percent of the respondents elected to keep all tests as they are, a fairly substantial minority voted to eliminate the squat jump, broad jump, and chinning bar tests. Any changes in this area would be at the discretion of civil service authorities. What has been uncovered here is an indication of discontent. Probably some sort of physical ability measures are needed for selection, but one wonders whether some measures might be developed which bear closer relation to the requirements of the job and which might be predictive of future physical condition.

Whatever decisions may be made regarding these and earlier suggestions, it is the hope of at least one researcher that the data presented herein may in some way improve the "policeman's lot" which, alas, is not a happy one.

## DEPARTMENT OF CIVIL SERVICE

ARNOLD CONSTABLE BUILDING
FRONT AND MONTGOMERY STREETS
RONT AND MONTGOMERY ST
TRENTON N. J. 08625

TO: Chiefs of Police in Selected New Jersey Communities
SUBJECT: Physical Activities Survey

As part of its continuing program for upgrading selection procedures the Department of Civil Service, in association with the State Law Enforcement Planning Agency, has arranged for macational Testing Service to conduct a survey of phe performance tests and related matters.

As Chief of Police of one of these selected communities for this study, your cooperation, and that of the men in your command, is being requested. Your assistance will result in findings which can be beneficial to police departments throughout the state.

Wayne S. Boyd
Director of Examinations

## Dear Chief:

The New Jersey State Department of Civil Service, in cooperation with the State Law Enforcement Planning Agency, has requested Educational Testing Service to conduct a survey of policemen in order to collect information which will be helpful in evaluating physical performance tests now used for selection of police candidates.

Through the use of random sampling methods, your community has been selected for participation in this study. Your cooperation can help it succeed.

Please have the accompanying questionnaire forms distributed to a sample of men in your command. The men are to be instructed not to put their names on the forms; all responses are to be anonymous. It will take approximately ten to fifteen minutes to fill out a form. All completed forms should be returned to ETS in the enclosed postage-paid envelope.

If you wish to receive a copy of the final report of this study, please fill out and return the enclosed form in the envelope with the completed questionnaires. I will be pleased to answer any questions you may have about this study. Please have the questionnaires returned by $\qquad$ . Thank you for your interest and cooperation.

Leo S. Goldstein, PhD
Research Psychologist

## PHYSICAL ACTIVITIES SURVEY

## Directions for Administration

*1) Assemble a sample of men in your command, in one central location. Include representatives of all ranks, if possible.
2) Instruct the men to write their answers to all questions on the form. Remind them not to put their names on the form; all replies are to be anonymous.
3) The back of the form is to be used to describe any recommended changes in the present civil service physical performance test. Any additional comments concerning the questionnaire, physical performance testing or related matters should also be written on the back of the form.
4) When everyone in the group has completed filling out the form appoint one member of the group to collect all forms, insert them in the enclosed return envelope, and seal the envelope Insert the request form for a copy of the final report in the envelope before it is sealed.

The number of men sampled should equal the number of questionnaire which have been sent in this packet. If the entire sample cannot be assembled at one session, additional sessions should be held.

Please send me a copy of the final report of the Police Physical Activities Survey

| 12 | 0 | 0.0 | 0.0 |
| Total | 1715 | 100.0 |  |

## Table 19

Number and percent of police officers in PAS sample indicating presence of 12 specific physical symptoms or diseases.

| Symptom or Disease | N |  |
| :--- | :---: | ---: |
| Hemorrhoids | 282 | 16.4 |
| Lung Disease | 20 | 1.2 |
| Back Trouble | 411 | 24.0 |
| Loss of Teeth | 353 | 20.6 |
| Varicose Veins | 55 | 3.2 |
| Heart Disease | 52 | 3.0 |
| Flat Feet | 33 | 1.9 |
| Hernia | 127 | 4.7 |
| Ulcer | 151 | 7.4 |
| High Blood Pressure | 124 | 8.8 |
| Nervous Disorder | 182 | 7.2 |
| Other | 1870 | 10.6 |
|  |  | $109.0 *$ |

*Multiple responses account for more than $100 \%$ response.

Number and percent of PAS sample reporting importance of physical condition for the job.

| Importance | N | \% |
| :--- | ---: | ---: |
| Very important | 1287 | 69.0 |
| Average | 537 | 28.8 |
| Little importance | 42 | 2.2 |
|  |  |  |
| Total | 1866 |  |

## -51-

## Table 21

Number and percent of PAS sample reporting frequency of exercise.

| Frequency | $\underline{N}$ | $\%$ |
| :--- | :---: | :---: |
| $4-7$ times a week | 298 | 21.5 |
| $1-3$ times a week | 583 | 42.1 |
| Irregularly | 488 | 35.2 |
| Never | 16 | 1.2 |
|  |  |  |
| Total | 1385 | 100.0 |

Table 22

Importance of physical condition in relation to regularity of exercise for PAS sample responding to both items.

| Importance | Regularity |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 4-7/week |  | 1-3/week |  | Irregular |  | Never |  |
|  | N | \% |  | \% | N | \% | N | \% |
|  |  |  |  | 45 | 313 | 30.4 | 6 | 0.6 |
| Very | 248 | 24.1 | 463 | 45.0 |  |  |  |  |
|  | 48 | 14.6 | 109 | 33.2 | 163 | 49.7 | 8 | 2.4 |
| Average |  |  |  |  |  | 40.9 | 2 | 9.1 |
| Little | 2 | 9.1 | 9 | 40.9 | 9 | 40.9 |  |  |
| Total | 298 | 21.6 | 581 | 42.1 | 485 | 35.1 | 16 | 1.2 |

Number and percent of PAS sample of police officers routinely performing one or more of specified exercises.

| Exercise | $\underline{N}$ | $\underline{\%}$ |
| :--- | :---: | :---: |
| Lift weights | 295 | 16.0 |
| Calisthenics | 690 | 37.4 |
| Jog | 378 | 20.5 |
| Swim | 468 | 25.3 |
| Other | 675 | 36.5 |
|  |  |  |
| Total | 2506 | $135.7 *$ |

*Multiple responses account for more than $100.0 \%$ total.

## Tab1e 25

Number and percent of PAS sample electing to keep, eliminate or change Civil Service physical performance tests.
