ACQUISITIONS

Highlights of the Report

Fire is one of our Nation's major problems. Each year it causes thousands of deaths, hundreds of thousands of injuries, and billions of dollars of property loss. It causes more loss of life and property than all natural disasters combined. In the home it is the second most frequent cause of accidental death. If a "catastrophe" is defined as an event that causes five or more deaths at one time, fire is the catastrophe that occurs most frequently in this country.

If we are to reduce fire losses as much as we can as a Nation, fire departments across the country, Federal and State governments, and others active in the fire protection field need to more clearly identify their fire problems and continually evaluate their priorities for action, priorities that compete for staff time and funds. They need to identify what works and what does not work, and to target programs more accurately. To do these tasks well, they need more detailed, more reliable information than has been available to date.

Objectives of This Report

This report is intended to provide part of the information that is needed for the above purposes. As a by-product, it illustrates ways that State and local governments might analyze their own fire problems. It is the first in what is planned to be an annual series.

The report describes the magnitude of the national fire problem in terms of numbers of fires, deaths, injuries, and dollars lost. It also describes specific characteristics of the fire problem, such as who are the victims and what are the causes of fires in various types of property. Although some suggestions for reducing the fire problem are included, the reader is encouraged to formulate his own.

Better Fire Data Needed

Before discussing findings, we must emphasize that the fire data currently available leave much to be desired in completeness, accuracy, and comparability—especially for rural sections of the United States. This report is uneven in detail on different aspects of the fire problem largely due to deficiencies in the available data when we began our analysis. The most detailed data on fire causes were available for a full year only for two States—California and Ohio. A few other States had detailed data, but not in a form that was easily comparable. The limited State data available this year were supplemented by data from seven cities (in other States) with compatible data systems.

In spite of the shortcomings, however, we think that the available data accurately characterize some major aspects of the U.S. fire problem. Sources drawn upon for this report included the following: National Fire Protection Association (NFPA); Center for Health Statistics of the U.S. Department of Health, Education and Welfare (HEW); insurance industry; National Fire Incident Reporting System (NFIRS) of the National Fire Prevention and Control Administration (NFPCA); National Household Fire Survey; and State Fire Marshals' reports.

Improved fire data is likely in the near future. More and more State and local governments are upgrading their fire data collection programs. Participation in the National Fire Incident Reporting System is growing. And more attention is being paid to fire data at all levels of government. But there is clearly still a long way to go.

Some of the key findings in this report are summarized below. Except where otherwise noted, all the findings are based on information about fires that were attended by the fire service. References in parentheses below indicate where each finding is given in the report.

National Estimates Show Severe U.S. Fire Problem

In the mid-70's the Nation's annual fire experience was approximately as follows:

FIRES	2,600,000	Reported to Fire Service
	30,000,000	Not Reported to Fire Service
	32,600,000	Total
DEATHS	7,500	
INJURIES	110,000	Reported to Fire Service
	200,000	Not Reported to Fire Service
	310,000	Total
DOLLAR LOSS ..	4.2+	Billion Direct Property
	\$ 9.4+	Billion Other Costs
	\$13.6+	Billion Total
See Part I Section II for data interpretation notes.		

When these U.S. statistics are compared with those from other industrialized countries, our fire incidents, casualties, and dollar loss *per capita* are found to be among the highest in the world. U.S. casualties and losses *per fire*, however, are slightly below average compared to other countries. These results support the increasing belief that in order to make a major dent in the national problem we need to emphasize better fire prevention. (Part 1, Table 8)

Estimates for the above U.S. statistics differ widely from source to source, sometimes by 50-100 percent. This variation is a result of different methods and assumptions used in collecting and analyzing the data. (Examples of the variation for each estimate are given in Part I, Table 2.)

Fire Deaths Are Highest in the Home

- Residential fires are the main killer and should receive high priority in prevention programs if we are to reduce fire deaths significantly.

We think that the use of smoke detectors, coupled with escape plans, is one of the promising ways to reduce this toll.

- Roughly two-thirds of fire deaths occur in residences, mostly in ones and twos in the victims' own homes. However, the less than 4 percent of fire deaths that occur in multiples of five or more draw the most attention. As a result, the residential fire danger probably is underestimated by the public.

- Only a small fraction of deaths (for example, 7 percent in California and Ohio) are in commercial or institutional places such as nightclubs, schools, jails, offices, or nursing homes. We should not, of course, permit these statistics to let us get complacent about the threat of fire in public buildings lest we invite more frequent catastrophes such as the 1977 Southgate, Ky., nightclub fire. (Part I, Tables 13 and 18)

Who Dies

- Among civilians (that is, anyone not a firefighter), males (especially nonwhite males), the very old, and the very young are high risk groups that fire prevention should focus on. While the problem of high fire death rates among the elderly, children, and nonwhites has long been known, the predominance of males as victims has not. This problem deserves more attention in prevention programs than it has received.

- Nationwide, males outnumber females almost two to one as fire death victims. Nonwhite males have more than twice the fire death rate of white males and almost twice that of nonwhite females. And nonwhite females have almost three times the rate of white females. (Part I, Figure 2)

- Firefighters have the Nation's most hazardous profession in terms of death rates. Not surprisingly, they also have the highest fire death rate for any group in our society—it is over 25 times that of civilians. Firefighter on-duty deaths are most often (45 percent) caused by heart attacks and other cardiovascular problems, which suggests the potential importance of improving fire service physical fitness programs. (Part I, Table 5 and Section IV)

WHERE FIRE DEATHS OCCUR

Source: California (CFIRS 1975), Ohio (NFIRS 1976).

FIRE DEATH RATES BY RACE AND SEX — 1974

Who Gets Hurt

- Unlike deaths, the risk of fire injury is highest for those in the 18-35 age group, and not the very young and very old. This may be due to a greater number of exposures to danger for people in their most active years, but an increased ability to escape with minor injuries when exposed. (Part I, Table 28)

- For civilians in Ohio, the only State for which we have injury data by sex, about the same two-for-one male-female ratio is true for injuries as for deaths. Male injury victims outnumber female victims not only overall, but also for every

age group under 65. (Part I, Figures 2, 12; Part II, Table 27)

- Civilian fire injuries are largely due to burns or "smoke" inhalation or both (83 percent in Ohio). As was noted for civilian deaths, smoke detectors offer good potential for reducing these injuries. Further research is needed on the relative frequency with which the various components of "smoke" caused either death or injury as a guide to both prevention and medical care. (Part I, Table 12; Part II, Table 32)

- Firefighter injuries also require more attention in research and prevention than they have

CIVILIAN NON-FATAL INJURIES BY AGE AND SEX

Source: Ohio (NFIRS 1976).

CIVILIAN NON-FATAL INJURIES BY NATURE OF INJURY

Source: Ohio (NFIRS 1976).

received if we are to reduce the Nation's fire injuries significantly. Firefighters incur over half of the injuries sustained at fires they attend. This nationwide estimate is supported by the detailed analysis of data from Ohio (56 percent) and in seven cities elsewhere (54 percent). (Part I, Table 5; Part II, Table 32)

- Firefighters need an across-the-board improvement in their protective clothing. They need to make greater use of breathing apparatus. They need to achieve and maintain a higher level of physical fitness. And they need better fire safety training. "Smoke" (often carbon monoxide) inhalation seems to be the most common type of firefighter injury. In Ohio, for example, smoke inhalation accounted for 25 percent of incident-related injuries to firefighters, followed by strains and sprains (17 percent), cuts or wounds (17 percent), and burns (11 percent). (Smoke and burns combined were another 4 percent.) Firefighter injuries other than smoke inhalation were distributed roughly evenly over the body. (Part I, Table 5; Part II, Tables 29, 31, 32)

It should be noted that the injury data—both for civilians and firefighters—are of much more questionable accuracy than fire death data. The major uncertainty probably is the degree of

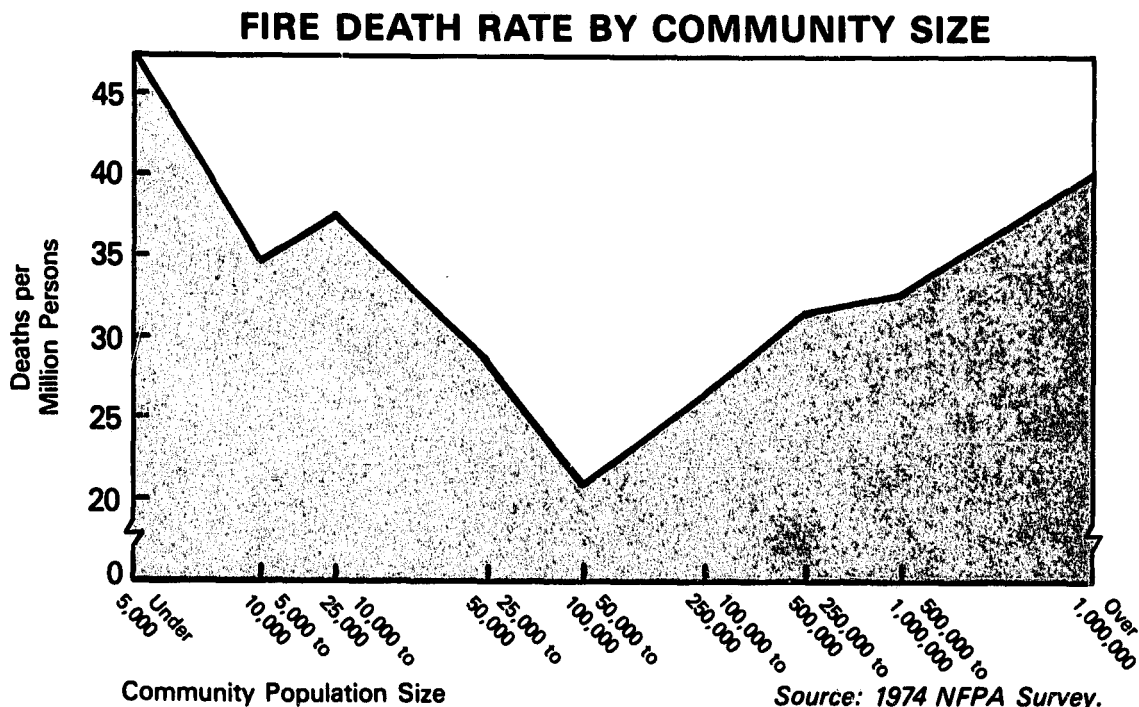

under-reporting (though in some cases, over-reporting) of minor injuries.

The Problem Varies by Location

- Overall, the fire death problem seems more severe both in large cities and in rural communities than in mid-sized communities. Fire death rates plotted versus population size have a U-shaped pattern, with a low in medium-sized cities (50-100,000 population) and highs in cities of over a million population at one extreme and in small towns and areas of under 5,000 population at the other, according to NFPA 1974 survey data. Supplemental data gathered from cities over one million population indicate that the big city fire death rate may be even higher than shown in the figure, perhaps exceeding 50 deaths per million on the average. (Part I, Figure 4)

Patterns for fire incidents, injuries, and dollar loss are more complex and less reliable than for deaths, and are not easily summarized. (See Part I, Figures 4 and 14 for the patterns.)

- Statewide fire death rates are highest in Alaska and Maine and the belt of Southern States from Oklahoma, Arkansas, and Louisiana through Tennessee, Mississippi, Alabama, Georgia, and the Carolinas (over 42 deaths per million in

each State). The fire death problem in these States is serious during the period considered. However, in any given year, a State just by laws of chance may have a high fire death rate.

- State and local governments should analyze their own fire problems and not rely on analyses from others. National trends and regional similarities exist, but there are also striking differences from place to place. To cite one example for residential fires, some of the six Ohio cities with over 200,000 population had smoking-related fires far outnumbering cooking-related fires, some had the reverse, and some had both about the same. In some of these cities arson outnumbered both cooking and smoking as a cause of residential fires; in others arson was lower than both. While

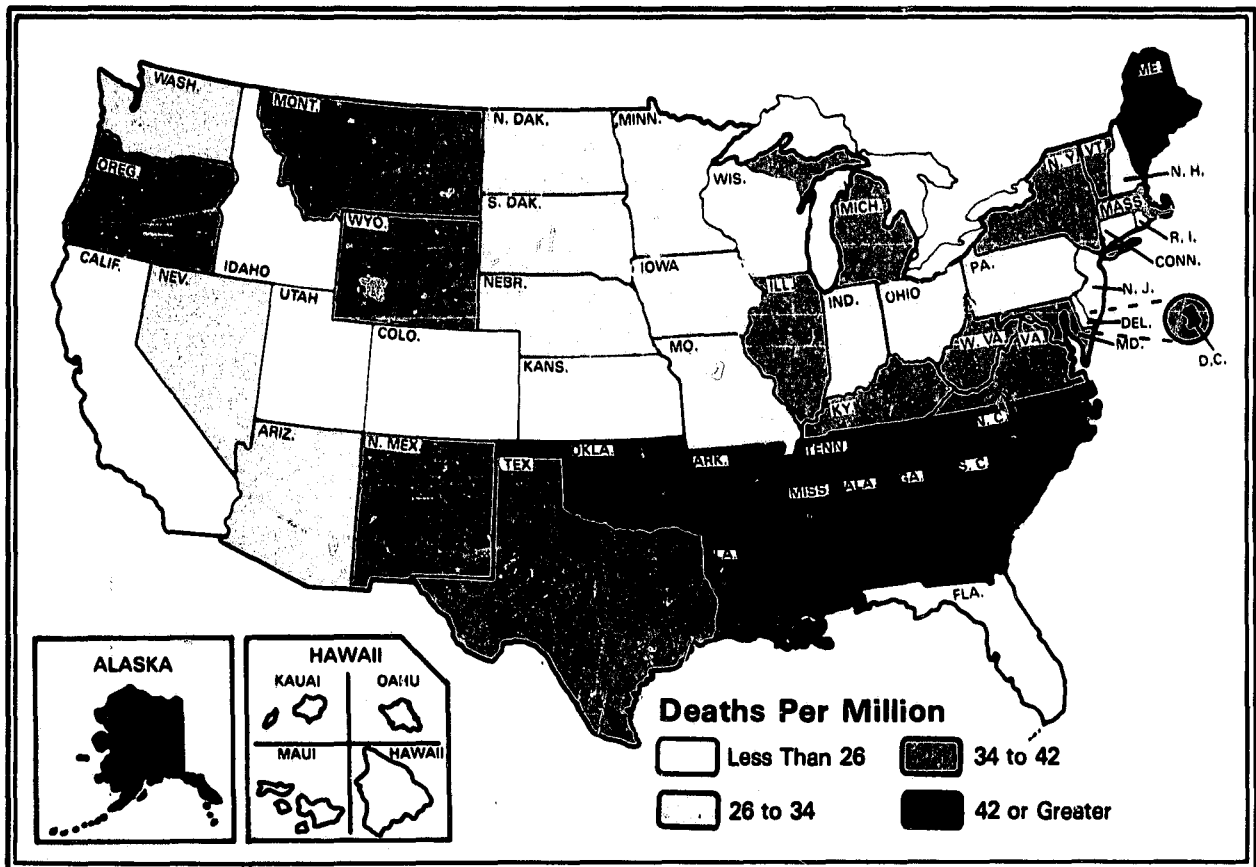

some of the variation might be due to differences in reporting procedures, some of it is probably real. Each community should try to identify its own priorities and to learn why it differs from others. (Part II, Table 48)

Deaths Trend Downward, Dollar Loss Upward

- The annual U.S. fire death rate has declined slightly during the last 20 years, though it is still among the highest in the world. We did not find adequate data for assessing trends in injuries. (Part I, Figure 10)

- Direct dollar loss from fire, adjusted for inflation, has about doubled over the last 20 years. Per capita dollar loss, also adjusted for inflation,

STATE FIRE DEATH RATES — DEATHS PER MILLION POPULATION (AVERAGE 1974-75)

Source: State Fire Marshals and National Center for Health Statistics.

has increased by about 40 percent over this same period. But, overall, losses have remained a fairly constant percentage of the Gross National Product. (Part I, Figures 7, 8, and 9)

Eight Cause Categories Predominate

For the two States examined in detail—Ohio and California—and seven additional cities with comparable data systems, the leading causes of fire are described below. These data may or may not be representative of the entire United States; they collectively represent about 15 percent of the U.S. population, but are not a random sample. In general, the cause pattern was quite similar in the two States and the seven cities.

In the two States combined, **residential fires** are only 22 percent of all fires attended by the fire service; but they account for 68 percent of deaths, 57 percent of injuries, and 43 percent of dollar loss. (Part I, Table 13)

- The eight major “known” cause categories of residential fires in the two States combined are, in order of frequency: cooking (18 percent), smoking (13), heating (13), incendiary or suspicious (11), electrical distribution (7), appliances (7), children playing (5), and carelessness with open flames or sparks (5). These general “cause” categories are shorthand for groups of more complex causes. The percentages shown in parentheses are of all fires attended by the fire service, not just “known cause” fires. The actual percentages thus may be somewhat higher, depending on the true causes of the 10 percent of fires listed as “unknown.” (Part I, Figure 13)

- Among cooking fires, cooking left unattended (for example, while talking with neighbors or watching TV) was the most common problem. For smoking-related fires, dropped, thrown, or abandoned cigarettes were the most common problems. For heating-related fires, there appear to be sharp regional differences in the nature of the problem: Failures of central heating systems and construction of deficiencies in fireplaces lead a wide variety of mechanical and operational problems in Ohio; “combustibles stored too close” to fixed room heating equipment and water

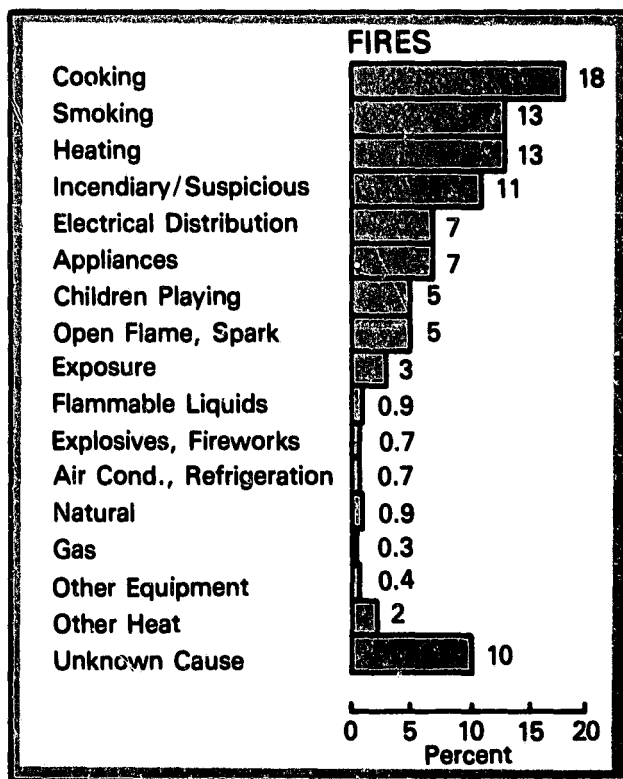

heaters, and, surprisingly, “misuse” of fireplaces are among the leading heating-related problems in California. (Part II, Tables 38, 35, and 40)

- The most frequently reported cause of residential *deaths* (29 percent) and *injuries* (18 percent) in the two States is smoking, mostly cigarettes igniting bedding, mattresses, or upholstered furniture.

The second most frequent cause of residential fire deaths and injuries in the two States, surprisingly, is cooking fires (9 percent of deaths, 13 percent of injuries). Although most people probably think of cooking fires as minor, they occur frequently; and the small fraction of them that are not minor cause a large number of casualties.

Heating-related fires (8 percent of deaths, 12 percent of injuries) and incendiary/suspicious fires (6 percent of deaths, 12 percent of injuries) are close behind cooking as third and fourth causes of casualties.

CAUSES OF RESIDENTIAL FIRES

Source: California (CFIRS 1975), Ohio (NFIRS 1976).

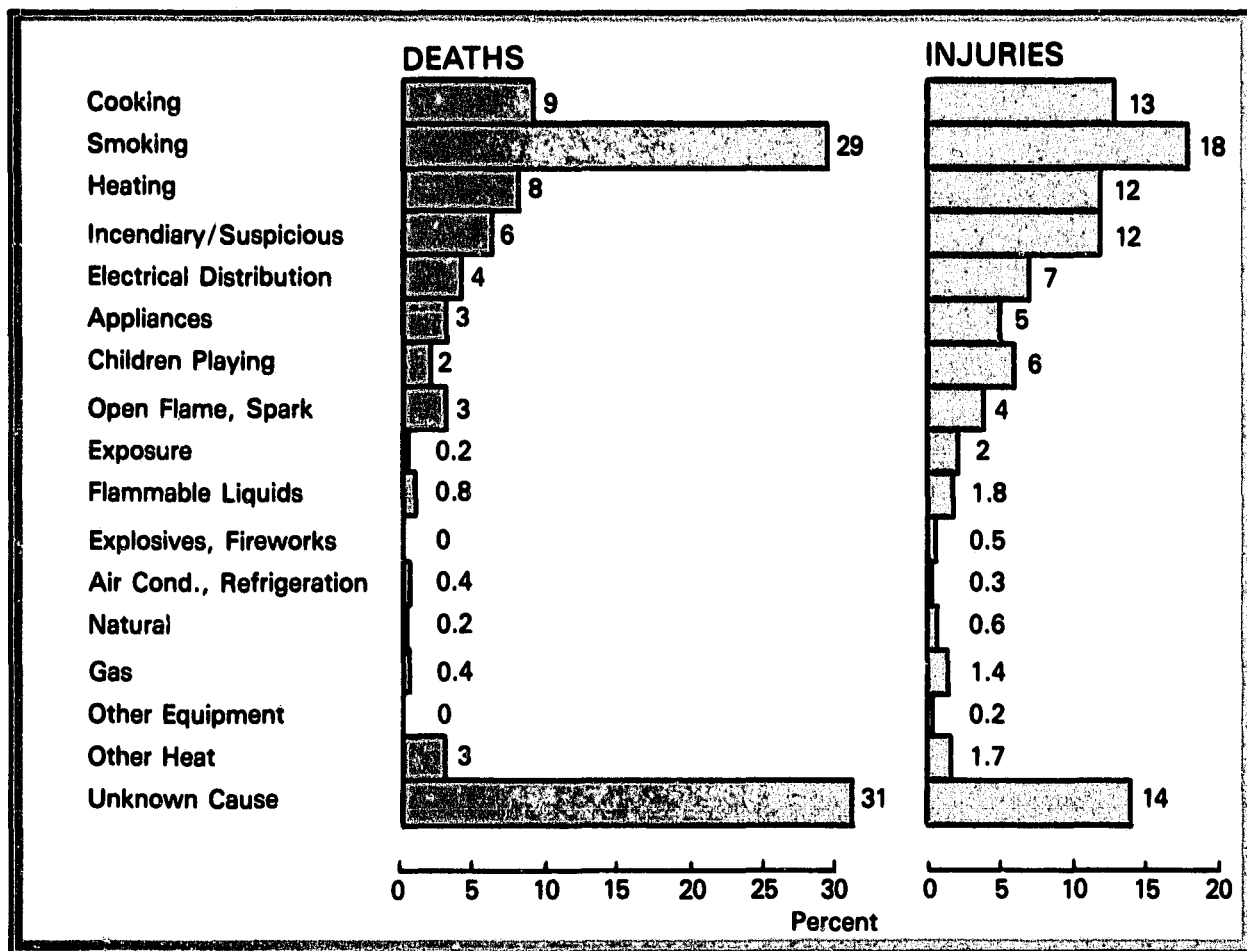

Again, percentages here are of total fire deaths, not just those with a known cause. Actual percentages may be considerably higher depending on the true nature of the "unknown cause" deaths—an enormous 31 percent in these two States. (Part I, Figures 13; Part II, Table 33)

- The known cause accounting for the most dollar loss is incendiary/suspicious fires (16 percent). Next highest is heating-related fires (14 percent). (Part I, Figure 13)

- Better fire investigation and reporting practices are needed to reduce the number of fires

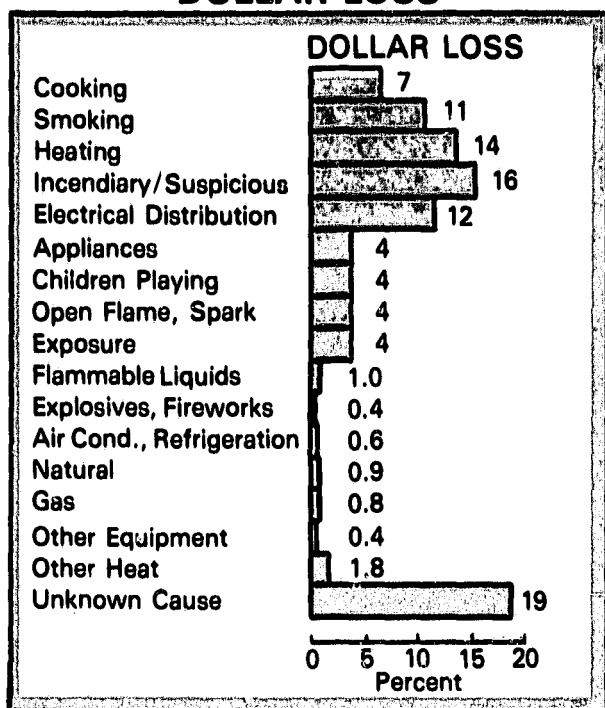

with cause listed as "unknown." There always will be some fires for which the cause will be unknown, but the fraction today seems excessive. "Unknown" is the leading cause category in the two States for deaths (31 percent) and dollar loss (19 percent), second for injuries (14 percent), and fifth for the number of fires (10 percent). Although the known causes discussed above clearly are important ones, their rank ordering could change significantly depending on what the "unknown" causes actually are. (Part I, Figure 13)

CAUSES OF RESIDENTIAL FIRE CASUALTIES

Source: California (CFIRS 1975), Ohio (NFIRS 1976).

CAUSES OF RESIDENTIAL FIRE DOLLAR LOSS

Source: California (CFIRS 1975), Ohio (NFIRS 1976).

Non-residential building fires in the two States account for only 10 percent of all fires, 7 percent of deaths, 26 percent of injuries, but for 43 percent of dollar losses—tied with residential dollar loss (Part I, Table 13). Non-residential buildings cover an enormous range of structures and uses and probably should not be viewed as a single category. Principal causes vary considerably for different types of non-residential buildings, and prevention efforts should be tailored to the leading causes in each.

• Overall, incendiary and suspicious fires are the number one problem for non-residential buildings. They account for 20 percent to 25 percent of non-residential building fires, deaths, injuries, and dollar loss. "Unknown" is the second most frequent cause reported (13 percent). The next most frequent cause categories are electrical distribution fires (11 percent), carelessness involving open flames or sparks (8 percent), and smoking related fires (8 percent). As with residential, the unknowns could change the rank orderings. (Part I, Table 18)

• For each category of non-residential occupancies, in the two States, the leading causes are shown below. More than one cause is listed when one alone did not dominate:

Public Assembly	Cooking (mainly restaurants) Incendiary/Suspicious
Education	Smoking Incendiary/Suspicious in public day schools
Institutions	Smoking Incendiary/Suspicious
Stores, Offices	Incendiary/Suspicious Electrical Distribution
Basic Industry	Electrical Distribution (most- ly from fires in the energy distribution industry)
Manufacturing	Many assorted causes
Storage	Incendiary/Suspicious
Vacant, Construction	Incendiary/Suspicious

(Part I, Table 18; Part II, Section XI)

Unreported Fires Should Not Be Disregarded

Fires not reported to the fire service cannot be assumed to be trivial. About 9 out of 10 fires in households are not reported to fire departments, according to the 1974 National Household Fire Survey of 33,000 households. Most of these unreported fires involve cooking and are very small. However, the survey showed that almost half of the fires causing injuries severe enough to result in time lost from work were not reported to the fire service. And over half of the fires with more than a \$200 loss were not reported. Another survey in a year or two is needed to see if these results will still apply. (Part I, Section IV)

Findings Should Be Used to Reduce Losses

Knowledge of the most common causes of fires can be used in setting prevention priorities. The priority to be assigned to any particular cause is not necessarily its frequency rank, however.

Sometimes a greater reduction in fire loss can be achieved per dollar or man-year spent on preventing a lower ranking cause than a higher one, because of the difficulty in making progress on the higher one. And sometimes a group of citizens may have a disproportionately high casualty rate due to a cause that is not one of the most frequent ones community-wide. Priority setting must consider these productivity and equity issues as well as frequency of occurrence.

To reduce fire losses further, fire protection leaders, prevention officers, researchers, code makers, and others concerned with the Nation's fire problem can now make use of the improved information they called for. Making sure that fire prevention efforts are targeted accurately in each community is perhaps the most important "next step." When this is done, it will show the thousands of firefighters who are bearing the brunt of data collection that their efforts are paying off.

Acknowledgments

Several thousand local fire departments and tens of thousands of firefighters collected the raw data that were used in this report. Their efforts are greatly appreciated.

Special thanks for providing data go to the State governments of California and Ohio; to the local governments of Denver, Colo.; Jacksonville Fla.; Kansas City, Mo.; Madison, Wis.; Syracuse and New York, N.Y.; Tucson, Ariz.; Wichita, Kans.; Detroit, Mich.; Philadelphia, Pa.; Los Angeles City,

Calif.; to the National Fire Protection Association (NFPA), Boston, Mass.; and to the Insurance Information Institute, New York, N.Y. We also would like to acknowledge NFPA's assistance in undertaking new analyses of their 1974 survey data for us.

Many individuals reviewed early drafts of this report and provided valuable suggestions. We gratefully acknowledge reviews we received from the following:

Introduction

"Data Can Save Lives" . . . unfortunately, the opposite is also true—data can kill. Critical decisions affecting fire and life safety are being made every day. These decisions are being based on what are believed to be "the facts" . . . and those "facts" are the result of conclusions drawn from the data YOU ARE—or are not—REPORTING . . . ACCURATELY. Think about it.

PHILIP C. FAVRO
California State Fire Marshal¹

Fire is one of our major and often unrecognized national problems. U.S. fire losses and casualties are high, both in absolute numbers and relative to other nations. Developing effective ways to reduce the problem requires better understanding of its dimensions and characteristics. In an age when fire protection agencies cannot obtain resources adequate to do everything well, we must have the best possible information to target available resources as efficiently as possible. As the quote above implies, not having adequate data can result in avoidable deaths and injuries due to mistargeted programs.

Background

This report has been written in partial fulfillment of the requirements set forth in Section 9 of the National Fire Prevention and Control Act, Public Law 93-498. According to Section 9, the National Fire Data Center was established specifically to provide an accurate, nationwide analysis of the fire problem, identify major problem areas, assist in setting priorities, determine possible solutions to problems, and monitor the effectiveness of programs to reduce fire losses. This report is the National Fire Data Center's initial

effort to address the above requirements. It is the first of an annual series of reports by the Data Center designed to provide a comprehensive, continuing description of the fire problem in the United States.

To assure that key data about each fire are collected in a similar way from place to place and to help assure that the data get used for fire protection at local, State, and national levels, the Fire Administration established the National Fire Incident Reporting System (NFIRS).

NFIRS uses standard terminology and reporting forms developed by the Committee on Fire Reporting of the National Fire Protection Association.² One reporting form is filled out for each fire incident and another for each casualty. These reports provide information on frequency, causes, spread, and extinguishment of fires; number, nature, and causes of casualties; amount of direct property losses; and other relevant factors. Data on incidents other than fires also may be collected at the discretion of State and local fire authorities.

NFIRS depends on the voluntary cooperation of State and local governments. Local communities collect the data and send them to their State. The State processes the data and sends feedback reports to the local communities. State and local governments can use the data to guide fire prevention efforts and to answer a variety

¹ Favro, Philip C., "Introduction: Some Observations and Conclusions," in *Summary and Analysis—California Fire Incident Reporting System 1976* (Sacramento, CA: California State Fire Marshal, 1977), p. 3.

² The committee includes representatives from the fire service, industry, and Government agencies.

of questions about their fire problem and fire protection programs. Every three months the State sends a data tape to the National Fire Data Center in Washington, D.C. The Center analyzes the data from all participating States along with data from other sources to produce annual reports as well as various special studies.

By the end of 1977, 19 States were involved in various stages of developing the system; five—Ohio, California, Maryland, New York, and Missouri—were reporting data on a regular basis to the National Fire Data Center. Data from two of these States—Ohio and California—have been reported for over a year and are used as examples of detailed analyses of the fire problem in this report. The national estimates of total fires, casualties, and losses, however, were not based on NFIRS data this year because of the limited geographic coverage of the data. Instead, we used HEW Center for Health Statistics data (on deaths), State fire marshal reports, a new analysis of the 1974 NFPA Annual Survey, and other existing sources. As more States provide data over a full year, we will base the national estimates on that data source. Eventually, we hope all States and territories will participate in NFIRS.

Although new and still quite limited in scope, the NFIRS system has already been very useful. Information from the over 500,000 incidents now on file is shared with other Federal agencies to assist in a wide variety of fire-related issues such as consumer product safety, mobile home standards, and rural fire protection. The data have been used to answer numerous requests from industry, the fire service, and others about the Nation's fire experience. They have also been used by the National Fire Administration's program offices in assigning priorities and shaping plans. As data are uniformly reported by additional States over a longer period of time, NFIRS will become even more valuable.

Purpose and Uses

This series of annual reports has multiple objectives. The first is to provide a description of the magnitude and trends of the overall U.S. fire problem, and how it compares to other national problems and to the experience of other nations. This information indicates how well we are doing as a Nation in fire protection and provides a perspective for allocating resources to the fire

problem. It is probably true that the fire problem is underestimated by the public. It is also probably true that many people misunderstand the nature of the problem due to the attention given to spectacular or catastrophic fires.

The second objective of this series of reports is to detail the characteristics of the fire problem in terms of losses, causes, victims, times and places of occurrence, and other particulars. This information is essential in assigning priority ratings to fire protection programs. It also is needed to target programs to specific problems and to the population groups most in need of help. And, over time, it will allow evaluation of the success of the programs undertaken.

A third objective is to establish baseline data, national norms, and data from a variety of communities that States and localities can use to see how well they are doing relative to others. Comparisons are difficult to make accurately and often can be misinterpreted. They are important nonetheless. We will work toward providing data and methodology for communities to make meaningful and useful comparisons.

Data from individual communities invariably will show some communities being high and some low on a given type of measure. This variation leads to a fourth objective, related to the preceding one: to identify places with outstanding results in some aspect of fire protection to see if they resulted from programs that can be used by other communities; and to identify places which may need special assistance.

The fifth objective is to illustrate ways in which fire data can be analyzed by State and local governments, so they can learn more about their own problems. Developing useful analyses takes time and statistical expertise often not available in State and local fire services. By providing examples of national, State, and local data analyses meaningful to policy and operations, we hope to encourage more accurate and useful analyses in many communities.

A sixth objective is to provide information in support of various fire protection research activities, such as studies of the relationship of fires to community characteristics or studies of the expected benefits from improved fire resistance in certain materials.

A seventh and final objective is to provide an indication of the reliability of data used for the above purposes, by contrasting estimates from

various data sources and by providing estimates of confidence, precision, and accuracy where possible.

Obviously, meeting all of these objectives is a tall order. This first national estimates report does not meet each of the above objectives to the same degree, and meets none as completely as we would wish. Nonetheless, those are the ends toward which we are committed.

Scope

In principle, the scope of this series of reports includes all aspects of fire in the United States. We do present considerable data on the overall problem. However, in practice the limitations of available resources led us to emphasize the part of the fire problem faced by local governments, especially the part concerning fires in buildings. This focus includes the greatest human and property losses and the part of the problem most likely to be influenced by changes in public policy.

Availability of data also influenced the scope of this report. As a result, various aspects of the fire problem described here have different levels of statistical detail. For example, California and Ohio fire characteristics are described in more detail than those of other States because, as noted above, they were the only two States for which we had comparable data for a full year, and not because they were thought most representative. For some characteristics, only Ohio data were available. Although no claims are made about California and Ohio as typical States, they happen to be two good choices because together they contain about 15 percent of the U.S. population and a wide range of climates, community sizes, city ages, industry types, life styles, and other factors. As more States and more communities in each State join the National Fire Incident Reporting System, coverage will be greater and more even.

"Clean" data are not available for any single recent year for all purposes. We therefore present data from different years, mostly 1974, 1975, or 1976, in various tables and figures. The scope of each table and figure is described in the text.

The overall scope of the report is summarized below:

- Department Type: Paid and volunteer departments.
- Community Size: All.

- Geographic Scope: The United States in general. Ohio and California in most detail.
- Property Types: All—residential and non-residential structures, vehicles, outside fires.
- Fire Data: Incidents, deaths, injuries, direct dollar loss, "causes," selected other data.
- Period: 1974-1975 for national estimates; 1975-1976 for details of two States.
- Reported/Unreported: Mostly fires attended by the fire service; some data from a special study of unreported household fires.

Excluded from the report are data for:

- Industrial fires not reported to the public fire service (probably the bulk of fires in big industry).
- Federal government and military fires not reported to the public fire service.
- Fires involving U.S. (transportation) carriers or property outside the United States.

The scope of the analyses varies, as well as the scope of the available data. Because our purpose here is to present an overview of the fire problem, the analyses do not use every data element available, nor do they summarize data at the most detailed levels of the data base.³

Although the report shows a number of ways to analyze data that State and local governments might consider, it just scratches the surface of what can be done.

Validity and Proper Use of Data

Data validity is not a new problem for fire protection, nor for other government services. It is a problem that is being discussed more openly than ever before, however, in the hope of achieving improvements. For example, the Federal approach to measuring unemployment is under review. The FBI Uniform Crime Reports have been found to under-report major crimes to a degree that requires separate victimization studies to supplement them. The validity of national statistics on illegal drug dealing and usage is unknown.

The existence of these validity problems does not mean the data cannot be used. It does mean they must be used intelligently.

³ For example, data are summarized in this report by State for property types at one and two digit NFPA 901 codes, but not the third digit level. The National Fire Data Center can provide specialized computer reports from its data base at any level of detail in the NFPA 901 codes, upon request. Charges are at cost for this service.

A major objective of the National Fire Data Center is to improve and periodically evaluate the validity of fire data available at all levels of government. Toward this end, the information in this report is presented wherever possible with comments on its validity and precision.

One problem facing the readers of this first report is the confidence they can place in the results presented. Some results disagree with previously well-publicized "facts" about fires. Some findings are so elementary that they may be suspect for being "newly discovered." And some of the information here is based on a new data collection system using a complex coding scheme that has not been fully broken-in in each participating fire department.

Whether the validity of the data is adequate depends on the question being asked. In general, most of the major findings appear to have at least face validity, and a number of reasonableness checks are given in the text. These, plus the results of a recent independent study of the validity of the data in one State,⁴ suggest that the data presented in this initial report probably suffice to identify many major problem areas. The precision of the rank ordering of fire problems is not known, however.

One must be especially careful in using new data when making comparisons among communities. Meaningful comparisons are difficult to make even when data are reliable and complete because of differences in the characteristics of the fire problem faced by various communities. It is especially hazardous here because of differences in the completeness of reporting of fire data to the State and national levels. Given the complex validity situation, we are particularly

concerned about having the data on individual communities and States quoted without the necessary caveats. That would be grossly unfair and could discourage the fire service from making further advances in data collection.

Organization of This Report

To meet the needs of readers with different roles and interests, this report has been divided into three parts. Part I presents the overall national estimates and discusses both recent and long-term trends. Highlights from more detailed studies are also included.

Part II presents detailed statistical tabulations of significant characteristics of fires in Ohio, California, and seven cities in other States. Part II is directed primarily toward providing an understanding of the causes of fires and fire losses, insights for targeting fire safety programs, and data useful for fire protection policy decisions at the local and State levels. The analysis illustrated in this part is also intended to provide ideas to State and local governments wishing to analyze their own fire experience.

The Appendices discuss methods used to develop the national estimates and the quality of the data sources available; they also give more details on State and national estimates.

Readers' Comments Requested

We hope this report will provide a stimulus for State and local governments to upgrade the quality of their data, to make better use of the data, and to participate in the national data collection effort. There will be modifications and improvements in the methods of analysis employed for next year's estimates. We welcome comments on how to improve the usefulness and accuracy of this report.

PART I
National Fire Estimates and Selected Statistics

Section I

Introduction to Part I

The three main sections of Part I which follow will give the reader an overall picture of the fire problem in the United States. The purposes and contents of each section are:

Section II: National Fire Problem. To indicate the magnitude of the fire problem in the United States and to provide a baseline from which future progress in fire safety can be measured, this section compiles overall estimates of the Nation's fire losses. The national estimates presented are a composite of data from various sources.

Section III: Trends and Comparisons. To show whether the problem is getting better or worse, this section presents trends in the Nation's fire death rate, number of fires, and amount of direct property loss. To show how our country is doing

relative to others, a comparison is made with other Western industrialized countries. Finally, comparisons of fire to other causes of death, such as accidents, serve to place fire in perspective relative to other national problems.

Section IV: Selected Characteristics of Fires. To provide more precise information needed to target fire prevention, a detailed analysis is given for two States: Ohio and California. Findings summarized in this section include: the types and causes of fires, the differences in fire rates between communities, the importance of fire protection devices, and fire casualty characteristics. Principal results from the National Household Fire Survey are also summarized. More detailed analyses of the Ohio and California data are presented in Part II of this report.

Section II

The National Fire Problem

NATIONAL FIRE LOSSES

The National Fire Prevention and Control Administration's estimates of overall fire losses in the United States for 1975 are summarized in Table 1, below. The estimates represent a composite from several data sources which are described in more detail in the following pages. The year 1975 has been used rather than 1976 because the data for 1975 were more complete. For the purpose of making appropriate "baseline" estimates—the main concern here—the differences from year to year are not significant.⁵

⁵ As the National Fire Incident Reporting System becomes fully operational and the estimating methodology routinized, we can expect a shorter interval between the publication of the national estimates and the year for which they are made.

There were approximately 2,600,000 fires in 1975 that were reported to the fire service, and about 30,000,000 more that were not reported. Approximately 7,500 deaths resulted from these fires. In addition, about 110,000 injuries were reported to the fire service; another 200,000 injuries were not reported, although they may have been reported in part to hospitals. The estimated total dollar loss—excluding such indirect losses due to fire as temporary housing, lost wages, extra food expenses, and medical treatment, etc.,⁶—exceeded \$13.6 billion.

⁶ Estimates of these indirect costs for residential occupancies will soon be published in Munson, Michael J., and Ohls, James C., *Indirect Losses Arising from Residential Fires* (Princeton, NJ: Princeton University, forthcoming), Fire Administration Grant No. NFPCA-77007.

Table 1. NFPCA's "BEST" NATIONAL ESTIMATES OF U.S. FIRE LOSSES (1975)

Fire Losses			Approximate Rates
FIRES	2,600,000	Reported to Fire Service	1,200 per 100,000 persons
	30,000,000	Not Reported to Fire Service ¹	14,000 per 100,000 persons
	32,600,000	Total	
DEATHS	7,500		35 per million persons
INJURIES	110,000	Reported to Fire Service	520 per million persons
	200,000	Not Reported to Fire Service ²	940 per million persons
	310,000	Total	
DOLLAR LOSS	\$ 4.2 Billion Direct Property Loss		\$ 19.70 per person
			59.10 per household ⁴
	9.4 + ? Billion Other Costs ³		44.00 per person
			132.20 per household ⁴
	\$13.6 + ? Billion Total Cost		\$ 63.70 per person Total
			\$191.30 per household Total

¹ National Household Fire Survey indicates that only about 8 percent of all fires are reported to the fire service.

² America Burning: Report of the National Commission on Fire Prevention and Control, Richard E. Bland, Chairman (Washington, DC: Government Printing Office, 1973), p. 1. Also National Household Fire Survey. Some injuries not reported to the fire service may be reported to hospitals.

³ "Indirect" losses, such as medical costs, displacement costs, and building construction costs attributable to fire protection are excluded this year. See Appendix II for a breakdown of the "other" costs which are included.

⁴ There was an average of 2.9 persons per household in 1975. Source: U.S. Bureau of the Census, *Statistical Abstract of the United States, 1976 (97th Edition)* (Washington, DC: U.S. Department of Commerce, 1977), p. 38.

NOTES: The data are not from any single year due to differences among data sources. This will be improved in the future. Rates are based upon a 1975 Census population estimate of 213 million persons.

Of this total, about \$4.2 billion consisted of direct property loss and at least \$9.4 billion was attributed to other costs such as public fire departments, insurance overhead, and sprinkler systems. See Appendix II for a breakdown of the "other" costs which are included.

BASIS OF NATIONAL ESTIMATES

There are several sources that provide national summary fire data. The National Fire Protection Association (NFPA) makes estimates of incidents, deaths and injuries, and dollar losses. These are published annually in the *Fire Journal* and have been based on a mail survey of some 2,000 fire departments in the United States, information obtained from various agencies of the Federal Government, State Fire Marshals, and some local fire departments not reporting in the survey. These estimates will be termed the "NFPA composite" in this report, as opposed to the composite National Estimates developed by the Fire Administration. The 1974 NFPA survey data have been, in addition, analyzed in detail in a different way by NFPCA, assisted by NFPA.⁷ (See Appendix III.)

The National Center for Health Statistics (NCHS) of the U.S. Department of Health, Education and Welfare collects information from death certificates. The NCHS-published fire death figure is a count of deaths recorded as being caused by a fire, whether from a burn or another type of injury. Certain categories of fire deaths are intentionally omitted to avoid double counting or inaccuracies in other areas. For example, deaths by fire resulting from a motor vehicle accident are listed only under transportation accidents and not under fires. A detailed discussion of the NCHS data and of estimates of transportation fire deaths are contained in a separate National Fire Administration technical report.⁸

Data originating from local fire departments are summarized, in most States, in annual State Fire Marshal reports. Unfortunately, the summary data from many States are incomplete, and it is questionable whether the data can be directly added for making national estimates (with the

possible exception of the data on fire deaths). However, these figures are useful for making comparisons and for estimating trends. The details of the Fire Marshal report data are given in Appendix IV.

The Insurance Information Institute publishes an annual estimate of direct property loss, based on information supplied by the Insurance Services Organization (ISO). ISO gets information from its members, which include about half of the insurance industry, principally stock companies. The Insurance Institute estimates include allowances for unreported and uninsured losses, but certain classes of property not usually covered by fire insurance are omitted; for example, government property, timber, and standing crops.

The National Safety Council (NSC) also publishes estimates of fires, fire deaths, fire injuries, and direct and indirect fire losses in their annual publication *Accident Facts* along with other accident information. Their death estimates are obtained from NCHS data and their estimates of numbers of fires and direct fire losses are obtained from the NFPA. They make their own estimates of injuries and indirect losses. The NSC data were used in several charts and tables in this report, although they were not used directly in making the national estimates shown in Table 1.

Besides NSC, a number of other public and private agencies collect injury data: the National Health Interview Survey⁹ (interviews conducted by the National Center for Health Statistics), the Commission on Professional and Hospital Activities (data from hospital discharge records), the National Burn Information Exchange (data from burn treatment facilities), the National Electronic Injury Surveillance System (hospital emergency room data collected by the Consumer Product Safety Commission), and the National Ambulatory Medical Care Survey (data from physicians' visits, conducted by HEW). These injury data sources and others were investigated by the University of Michigan.¹⁰ While all of these sources contain some useful information, the overall conclusion of the Michigan report is that each contains at

⁸ Frstrom, Geraldine, *Fire Deaths in the United States: Review of Data Sources and Range of Estimates* (Washington, DC: National Fire Prevention and Control Administration, September 1977). Some major points of this report are discussed in Appendix V.

⁹ Not to be confused with the 1974 National Household Fire Survey, sponsored by National Bureau of Standards and Consumer Product Safety Commission.

¹⁰ Flora, Jarius D., et al, *Fire Data Methodology, Vol. I: National Estimates of Fire Injuries* (Ann Arbor, MI: Highway Safety Research Institute, The University of Michigan, 1978), Fire Administration Grant No. 76028.

least one major deficiency that limits its usefulness for making national estimates.

Basis of Fire Incident Estimate

Table 2 summarizes the individual national estimates from the various sources used in forming the Fire Administration composite estimate. The large differences among the estimates reflect the disparate methods and assumptions used in collecting and analyzing the data. The final NFPCA composite estimates are presented in terms of both a range of values and a single "best estimate." The reasons for the differences between the estimates and the considerations that led to the final values are discussed below.

Several factors account for the large differences between the 1974 NFPCA/NFPA survey estimate and the NFPA composite estimate of the number of fires attended by the fire service.¹¹ First, processing of the 1974 NFPA survey data included extensive editing to eliminate or correct those responses that had obvious errors or inconsistencies in terms of the new application of the data.¹² Second, the NFPCA/NFPA analysis stratified the survey data according to community population, so that each population grouping was given its appropriate weight in the total. The main result of doing this was to increase the weight given to medium size and small communities over that in the earlier NFPA analysis. Finally, the NFPA composite estimate included certain fires that were not reported to fire departments, but which insurance records showed to have involved substantial losses.

To provide a further check, data from several States whose reporting was considered relatively complete were examined. From these data, we estimated a range of 1,150 to 1,300 reported fires per 100,000 persons, selecting 1,200 as the "best estimate" on the basis of NFPCA staff judgment. We do not consider this approach satisfactory; better estimates will have to await improved data collection in the future.

Basis of Death Estimate

The NCHS count of fire deaths is perhaps the most accurate of any of the fire loss numbers. However, as noted previously, this count must be

¹¹ "Fires attended by the fire service" is approximately equal to fires reported to the fire service.

¹² It was necessary to evaluate the data quality in light of a new application for the data.

corrected for transportation fire deaths, primarily from motor vehicle accidents. The NFPA's widely quoted *Fire Journal* pre-1977 figures included an estimate of motor vehicle fire deaths based upon some earlier studies, whereas the current NFPCA estimate of about 550 to 800 deaths from fire in motor vehicles is based on more recent studies, as well as State data. Combining the NCHS estimates with the NFPCA automobile death estimates leads to an estimated range of 34.6 to 35.7 fire deaths per million persons, with a "best estimate" of 35.1 deaths per million. Observe that the estimate, based on the 1974 NFPA survey, of 36.7 deaths per million is practically identical to the adjusted 1974 NCHS estimate of 36.5 per million.

Basis of Injury Estimate

The large differences in the injury estimates in Table 2 are not easy to reconcile. A major difficulty encountered in the collection of injury data is in deciding which minor injuries are to be reported and which are too insignificant to report. There is apparently little uniformity in this regard. The low estimate for the 1974 survey data partly reflects the fact that the injury rates for rural and small town areas were estimated to be less than one-half the city rates (although this is based on inadequate data). When the sample data for the 1974 survey was extrapolated to the United States, the estimate for total injuries turned out to be only slightly larger than the number estimated by NFPA and the International Association of Fire Fighters (IAFF) for firefighter injuries alone. (See Table 5, page 19.) On the other hand, NFPA's composite estimate of total injuries is about twice the number of firefighter injuries, which is a relationship observed in data from many State and local jurisdictions. A reasonable estimate of the injury rate appears to be between 400 to 600 injuries per million persons, with 500 as the "best estimate."

Basis of Dollar Loss Estimate

Again, the differences between the various estimates are substantial and not easily reconcilable. A few large losses can have a big effect. In fact, 0.2 percent of all fires accounted for 14 percent of total losses.¹³ For many large-loss fires (mostly non-residential), the amounts es-

¹³ "Fires and Fire Losses Classified, 1975," *Fire Journal*, November 1976, pp. 17-19.

Table 2. COMPARISON OF NATIONAL ESTIMATES FROM VARIOUS SOURCES

Source	Year ¹	Fires		Deaths		Injuries		Dollar Loss		Remarks
		Number	Rate/ 100,000	Number	Rate/ Million	Number	Rate/ Million	Dollars (Millions)	Dollars/ Person	
NFPCA NATIONAL ESTIMATES	1975	2,556,000	1,200	7,500	35.1	106,500	500	\$4,150	\$19.50	
	Range of Estimates									
	1975	2,450,000	1,150	7,400	34.6	85,200	400	\$3,800	\$18.00

¹ U.S. population—1974: 211 million; 1975: 213 million.² Analysis by NFPCA of edited tabulations provided by NFPA.³ For the 1974 row, one-third of the data are for 1975; similarly, for the 1975 row, one-third of the data are for 1976.⁴ An adjustment was made by adding in the figures for the dollar losses from several categories of fires not included in the Insurance Information Institute loss figures. These include, for 1974, forests—\$169 million, transportation—\$354 million, crops—\$36 million, and Federal property—\$180 million; for 1975, forests—\$180 million, transportation—\$495 million, crops—\$38 million, brush, etc.—\$21 million, and Federal property—\$200 million. The Federal property loss estimates are from the Federal Fire Council; the other loss estimates are from NFPA.NOTES: The NFPCA National Estimates are given as a "best" estimate and a range. They are *not* simple averages of range compilations of the other sources. See text for methodology.

Estimates of fires, injuries, and dollar loss are almost entirely for fires attended by the fire service. Some sources made adjustments for some unreported fires, as discussed in the text.

**Table 3. COMPARISON OF DIFFERENT ESTIMATES OF YEAR-TO-YEAR CHANGES
(1974 to 1975)**

Source	Year	Fires		Deaths		Injuries		Dollar Loss	
		(Reported)		Number	Percent	(Reported)		Dollars (Millions)	Percent
		Number	Percent			Number	Percent		
NFPA Composite (<i>Fire Journal</i>)	1974- 1975	+123,000	+4%	+200	+1%	+8,000	+ 6%	+\$352	+ 8%
State Fire Marshals (Annual Reports)	1974- 1975 ¹	+ 40,000	+2%	+573	+8%	+8,210	+14%	+\$ 79	+ 2%
National Center for Health Statistics	1974- 1975			-235	-3%				
Insurance Information Institute	1974- 1975						{ Unadjusted { Adjusted	+\$370 +\$565 ²	+12% +14%
NATIONAL ESTIMATE OF CHANGE	1974- 1975	+ 77,000	+3%	-234	-3%	+8,000	+7.5%	+\$330	+ 8%

¹ For the 1974 data, one-third of the reports are from 1975; similarly, for the 1975 data, one-third are from 1976.

² An adjustment was made by adding in the figures for the dollar losses from several categories of fires not included in the Insurance Information Institute loss figures. These include, for 1974, forests—\$169 million, transportation—\$354 million, crops—\$36 million, and Federal property—\$180 million; for 1975, forests—\$180 million, transportation—\$495 million, crops—\$38 million, brush, etc.—\$21 million, and Federal property—\$200 million. The Federal property loss estimates are from the Federal Fire Council; the other loss estimates are from NFPA.

timated by fire departments may be much less than the final amounts settled through adjustment or litigation. Note also that the Insurance Information Institute (III) estimate includes losses from fires not reported to fire departments and excludes substantial losses associated with Federal property, forests, and transportation. These categories of loss also tend to be under-reported by fire departments. Federal and non-building property losses have been included in the NFPA's composite estimate and the adjusted Insurance Information Institute values. The 1974 III unadjusted rate differs only slightly from the 1974 NFPA survey and from the State estimate. (States with unreasonably low published fire rates or dollar loss rates were not used in the calculation.) A reasonable estimated range for 1975 total direct property loss (including unreported, non-building, and Federal) is \$18 to \$21 per person. Our judgment is that the "best estimate" is about \$19.50 per person.

It is apparent that the precision of the above national estimates of deaths, injuries, and dollar losses is low. We need more consistency and accuracy in State and local data collection methods to improve this situation.

ESTIMATED YEAR-TO-YEAR CHANGE IN FIRE LOSS

Year-to-year changes indicate whether the fire problem is getting better or worse. Because of the uncertainty in previous estimates of the Nation's fire losses, a relatively small change from one year to the next is difficult to detect with any degree of confidence. However, by comparing the differences between 1974 and 1975 for the same data sources, one may be able to obtain a better estimate of recent change than by comparing estimates from different sources.

Estimates of year-to-year changes from various sources are summarized in Table 3. The NFPCA composite estimates (bottom line) are that there was a small reduction in deaths (down 3 percent), a small increase in fire incidents (up 3 percent), and moderate increases in injuries (up 7.5 percent) and property loss (up 8 percent).¹⁴ Much of the property loss increase may be attributed to inflation. It is also possible that the increases in

fire and injury rates reflect improved reporting by communities rather than true changes.

NFPA did not consider its 1975 survey data sufficiently reliable to warrant the detailed analysis that was performed for the 1974 data, and thus year-to-year changes in it are omitted.

The year-to-year estimates given above were made in the following manner. For fire incidents, the percentage increase was taken to be the average between the change in the NFPA composite and the change in the State Fire Marshal report figure. For deaths, the NCHS estimate, thought the most reliable, was used. For injuries, the increase of about 8,000 shown by both the NFPA composite and the State Fire Marshal data was used as the national estimate of change and converted to a percentage. For dollar loss, the intermediate NFPA estimate was judged the most reliable; this was also consistent with using their value as the recommended National Estimate in Table 2.

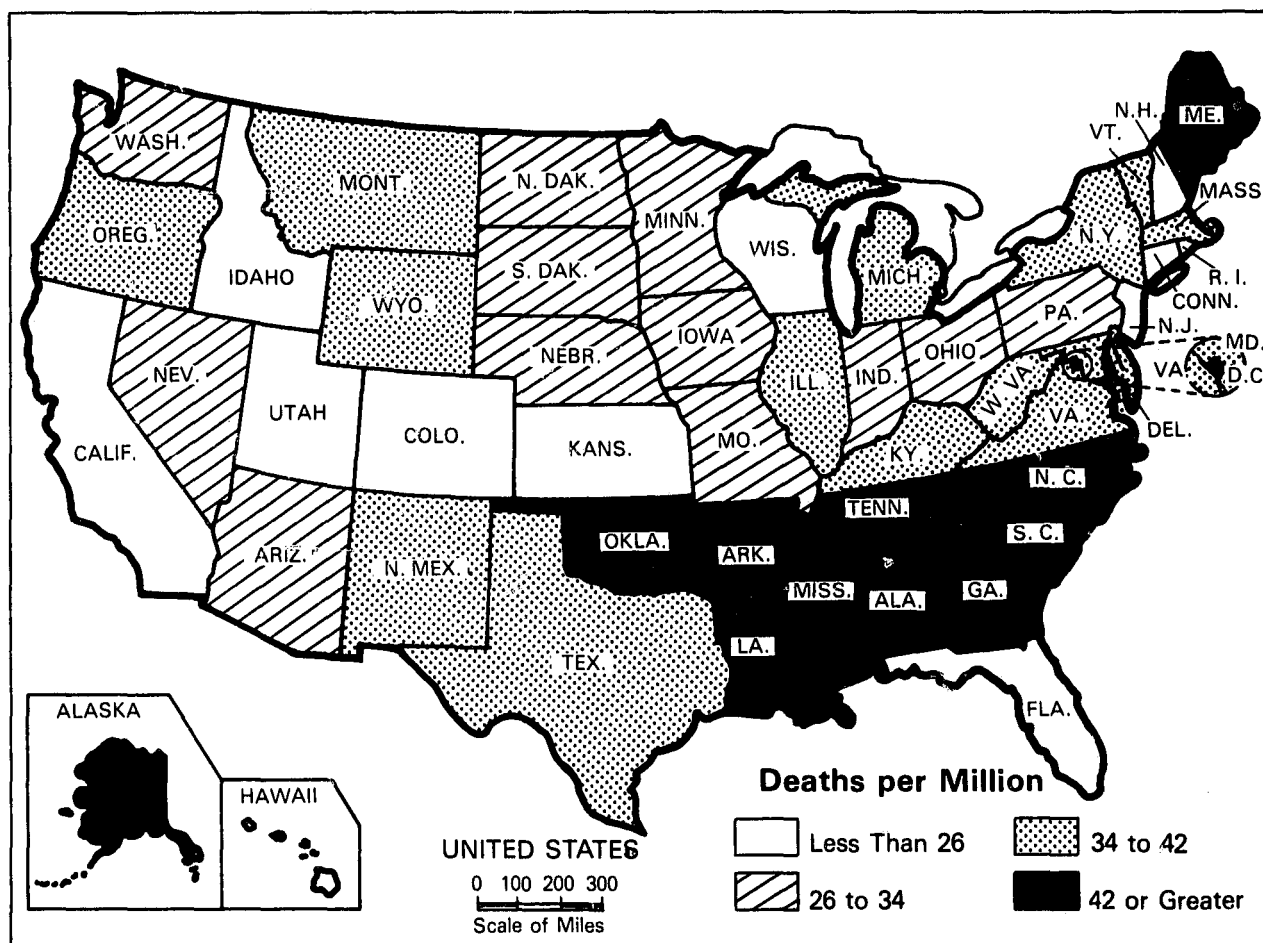

FIRE DEATH RATES BY STATES

Comparison of State fire death rates indicates whether the problem is more severe in some regions than others. The variation in death rates among States is shown in Figure 1. In general, the highest death rates occur in the Southeast; the lowest death rates occur in the West. There are, however, many exceptions. It would be useful to be able to explain why the problem in certain States is so much better or worse than in others, but we have not found satisfactory answers yet. Table 4 lists the States with highest and lowest death rates and indicates certain economic and social characteristics that may be pertinent. Since death rates fluctuate from year to year, especially for States with low population, for any one year they may not be representative. Because of this, for each State we took the larger of the death estimates from the State Fire Marshal and the Center for Health Statistics for 1974 and the larger for 1975, and then averaged those two numbers.

One of the sources for the National Estimates was State Fire Marshal Annual Reports obtained from 34 States and the District of Columbia. The quality of the State data varies greatly. Incomplete reporting of fire incidents to States from local governments occurs frequently, especially from small towns and rural communities.

¹⁴ The Insurance Information Institute reported that property loss in 1976 was about the same as for 1975.

Figure 1. STATE FIRE DEATH RATES — DEATHS PER MILLION POPULATION (CIRCA 1975)

SOURCE: Based on estimation of death rates by State for 1974 and 1975 given in Appendix IV, Table IV-4, except for New York which is based on the 1974 NFPA Survey.

We believe that records on the number of deaths are considerably more accurate. Moreover, preliminary tabulations of most of the death counts from the National Center for Health Statistics, excluding transportation fire deaths, have enabled us to correct death rates from several States and to obtain estimates for States for which we had no State Fire Marshal Annual Reports.

FIRE DEATH RATES BY SEX AND RACE

Males, nonwhites, and most strikingly, non-white males, have fire death rates much greater than the general population. This is shown in Figure 2. Males have an 80 percent higher fire

death rate than females. Nonwhite males have a fire death rate more than 50 percent greater than nonwhite females. Nonwhites have three times the fire death rate of whites.

While multiple problems associated with poverty and poor housing conditions undoubtedly contribute to the higher risk for nonwhites, they cannot explain the much higher risk of nonwhite males over nonwhite females. Greater likelihood of males to smoke and drink, to fight fires themselves, to work with and around gasoline, and to be involved in rescue efforts may be some possible reasons for their higher death rate. Future studies by NFPCA will be directed toward investigating these characteristics in order to

Table 4. STATES WITH HIGHEST AND LOWEST DEATH RATES

State	Average Fire Death Rate ¹ (1974-1975)	Per Capita Income Rank (1975) ²	Percent Completing High School (1970) ³	Percent of Families Below Poverty Level (1969) ⁴

³ *Ibid.*, p. 126. ⁴ *Ibid.*, p. 419.

better understand the reasons for the great disparities.

Fire prevention programs should be targeted toward these high risk groups, just as they have been for the elderly and children.

FIRE DEATH RATES BY PROPERTY TYPE

The distribution of deaths from fires in various types of properties is shown in Figure 3. Residential fires alone account for two-thirds of all deaths from fires. Deaths from residential fires in one- and two-family dwellings account for 44 percent of all deaths due to fires.

Certainly the residential fire problem must be tackled to reduce fire deaths significantly. We should not, of course, permit these statistics to let us get complacent about the threat of fire in

public buildings lest we invite more frequent catastrophes such as the 1977 Southgate, Kentucky, nightclub fire.

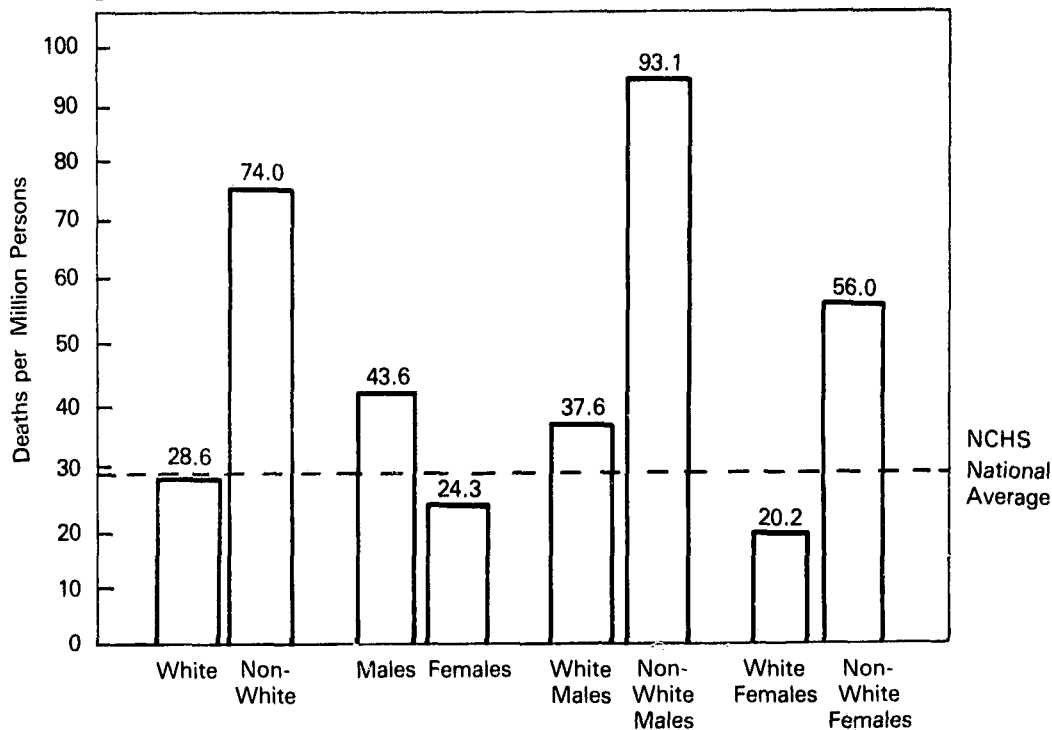

FIREFIGHTER DEATHS AND INJURIES

"Firefighters are ahead of all other occupations in death rates, making firefighting the most hazardous type of employment."¹⁵ Flames, falling walls, smoke, and motor vehicle accidents all take their toll, but the most frequent on-duty cause of death is heart attack.¹⁶

Figure 3. WHERE FIRE DEATHS OCCUR

¹This category includes mobile and outside properties, as well as other and unclassified properties.

SOURCE: Ohio 1976 NFIRS and California 1975 CFIRS data combined.

Injury rates for firefighters are also high—much higher than would be tolerated in other occupations. More than half the injuries from fires attended by the fire service are to firefighters even though there are many times more civilians exposed than firefighters. The firefighter is exposed to danger much longer and more frequently than the civilian.

Table 5 shows several estimates of firefighter deaths and injuries, including the International Association of Fire Fighters (IAFF) annual number of reported casualties for full-time firefighters. One hundred firefighter deaths were reported to the IAFF in 1974 and 108 deaths in 1975. The number reported to the NFPA in 1974 was about the same as that for IAFF, and slightly less than IAFF's figure for 1975. None of these counts are thought to be complete.

Full-time firefighter deaths have been estimated by the IAFF to be 90.7 per 100,000 firefighters in 1975.

To further illustrate just how serious that problem is, consider that the full-time firefighter death rate from fire is about 25 times that of civilians. And it is 10 to 20 times higher than that of the highest risk civilian groups—black males, the elderly, the very young.

A comparable fire death rate for all firefighters is difficult to arrive at and not attempted here because of uncertainty in the total number of volunteers, uncertainty in the number of deaths they suffer, and the difficulty of developing an equivalent full-time firefighter person-years estimate for the volunteers.

The number of firefighter injuries shown in the table confirms the hazardous nature of firefighting. There was one injury per year for approximately every two full-time firefighters in reporting jurisdictions. The trend in firefighter injuries is not clear. There were almost 9 percent fewer injuries reported to the IAFF in 1975 than in 1974. The NFPA estimate of total injuries (reported plus unreported injuries, including those to volunteers), was about 8 percent more in 1975.

A major effort is needed to reduce firefighter injuries. NFPCA has funded studies toward improving the physical fitness of firefighters,¹⁷ de-

veloping better protective clothing and breathing apparatus, and training firefighters in burn safety practices. (More details on firefighter injuries are given in Section IV.)

FIRE LOSSES VERSUS COMMUNITY SIZE: URBAN AND RURAL ESTIMATES

The urban fire problem has been highly publicized and deserves much attention. The rural problem has not received as much attention as it probably needs, especially since about 27 percent of the U.S. population is in rural areas. The relationship between fire loss rates and the population of the community served by individual fire departments is shown in Figure 4. The data are from the NFPA 1974 survey. Fires, deaths, and dollar loss per capita have roughly similar patterns of being high for the two extremes of the population—large cities and rural areas—and low in between. This phenomenon of middle-sized communities having less of a problem than the extremes is commonly found for many community services, not only fire protection.

More specifically, death rates for large cities and rural areas are about twice as large as for the 50,000 to 100,000 population interval. Data supplementing the survey on which Figure 4 is based, gathered from cities over one million population, indicate that the big city fire death rate may be even higher than shown, perhaps exceeding 50 deaths per million on the average.

Reported fire rates are lowest for small towns (5,000 to 10,000 population). Injury rates decrease with community size, falling sharply for communities of less than 10,000 persons (which on the surface is a paradox relative to the death rates). For dollar losses, the rates are quite low in the 10,000 to 250,000 population range and then surge by about 70 percent for communities below 10,000 population.

Figure 5 provides some insight into the U-shaped curve for per capita incident rate of fires (upper left hand graph in Figure 4). The large cities have a higher rate of fires than middle-sized communities mainly because of a higher rate of trash and residential fires. Rural areas have a higher rate than middle-sized communities primarily due to a higher rate of residential fires

¹⁷ Gratz, David G., and McCune, Dennis H., Principal Investigators, *Fire Service Physical Fitness Programs* (Washington, DC: International Association of Fire Chiefs Foundation, June 1977), Fire Administration Grant No. NFPCA-76025.

but also because of higher vehicle and non-residential building fire rates.

Residential fire deaths account for the majority of all fire deaths regardless of community size. The pattern of residential fire death rates in different size communities is similar to the pattern for all fire deaths. Figure 6 shows that both large cities and rural areas have a higher death rate in residential properties than do middle-sized communities. The death rate in public assembly properties increases sharply in rural areas. These two

factors account for the "U"-shaped appearance of the top curve of Figure 6.

The rural estimates are not very precise since comparatively few rural communities were sampled in the NFPA survey. This, together with the fact that rural areas comprise about 27 percent of the total U.S. population, results in the rural data contributing most to the overall statistical error in the national estimates. A more extensive rural survey would greatly improve the reliability of the national estimates and is planned.

³ "Industry, etc. Fire Deaths" includes basic industry, utility, defense, manufacturing, storage, and special properties.

Section III

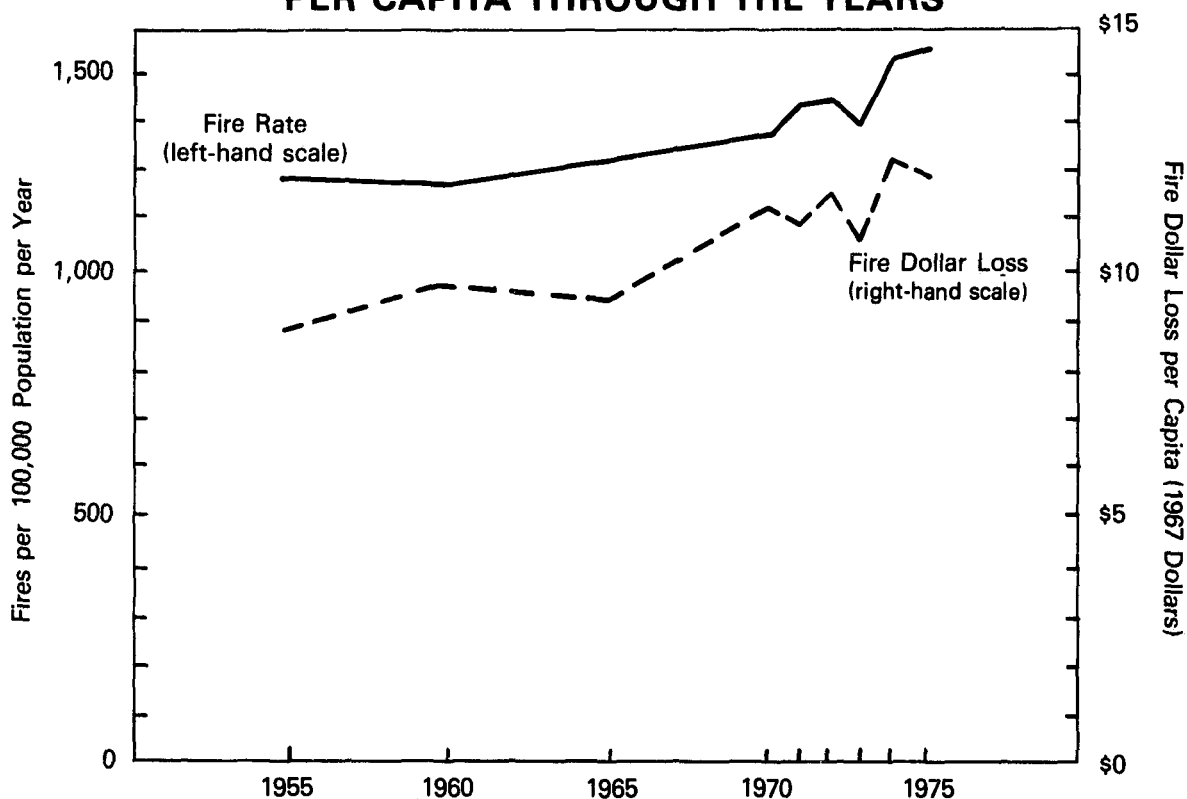

Comparisons: Other Years, Other Hazards, Other Countries

This section compares the U.S. fire problem today to that of other periods, other national problems, and other industrialized countries. These comparisons are intended to help put our fire problem in proper perspective, to help evaluate its importance, and to help determine the appropriate level of resources that should be directed toward a solution.

FIRE INCIDENCE AND LOSSES THROUGH THE YEARS

Per capita fire incident rates have increased by some 23 percent during the last 20 years (Figure 7). The per capita loss has increased about 40 percent over the same period, after adjusting for the effect of inflation by comparing figures on

Figure 7. FIRES AND FIRE DOLLAR LOSSES PER CAPITA THROUGH THE YEARS

SOURCE: Based on fire and fire loss estimates reported annually in "Fires and Fire Losses Classified", Fire Journal, National Fire Protection Association, Boston, MA, and population estimates from The Statistical Abstract of the United States, 1976 Bureau of the Census, p. 5.

a constant dollar basis. That is, losses have been rising faster than inflation and population—we are burning an increasing amount of property relative to our numbers.

Although the total amount of fire loss has increased several-fold (Figure 8), loss as a fraction of Gross National Product (GNP) has remained approximately constant (Figure 9). Since the GNP represents the total worth of goods and services our Nation produces, fire is claiming about the same share of our annual output. Taken together, these various loss trends imply that we have more things to burn and are therefore losing more when a fire occurs.

FIRE DEATHS THROUGH THE YEARS

Overall Fire Death Rates.—The overall fire death rate has declined significantly during the past 20 years. The data for 1955 through 1975 are shown in Figure 10. However, the U.S. fire death rate is still close to the highest, if not the highest, in the world, as discussed later. The U.S. problem is particularly severe for big cities, rural areas, the elderly, the very young, blacks, and males—as discussed in Section II.

Some reasons have been suggested for the declining trend including:

1. More buildings and equipment built with better passive and active fire protection, largely due to improved building and safety codes and the availability of better materials and equipment.
2. Increased public fire safety education.
3. More numerous, better trained, and better equipped public fire departments.

Death Rates for Catastrophic Fires.—The frequency of fires causing five or more deaths is shown in Figure 11. These fires are decreasing in number, in total persons killed, and in severity (average number of deaths per multiple death fire). Only three to four percent of fire deaths occur in such fires; most fire deaths occur in ones and twos in the victims' own homes.

Fire Death Rates by Age Group.—It has long been realized that the elderly and the very young suffer inordinately high fire death rates. For persons 65 years of age and over, the fire death rate has been about three times that of the general population; for children four years of age and under, about twice. In the past few years, the fire

SOURCE: Metropolitan Life Insurance Co., Statistical Bulletin, August 1971, and unpublished data, as reported in U.S. Bureau of the Census, Statistical Abstract of the United States, 1976 (97th Edition) (Washington, DC: U.S. Department of Commerce, 1977), p. 67.

Figure 12. FIRE DEATH RATE BY AGE GROUP, 1966-1975

SOURCE: National Safety Council as reported in Insurance Facts, 1976, Insurance Information Institute, New York, NY, 1976, p. 35.

death rates for both groups have been reduced significantly, although they are still much higher than for the population at large (Figure 12). It is not definitely known what caused the improvement, but there has been much fire prevention program effort expended toward this end. Government at all levels and many private organizations have worked to improve fire safety of nursing homes and housing for the elderly and to require that children's clothing be fire resistant, for example.

INCENDIARY FIRES THROUGH THE YEARS

There has been a sharp increase in the reported number of incendiary fires over the last 10 years. Table 6 shows the number of building fires where incendiarism was detected or suspected. To these must be added the undetected and unsuspected incendiary fires, plus fires of incendiary origin occurring in transportation vehicles, crops and wildlands, and outside of buildings. Incendiarism has become one of the most serious fire and crime problems. Part of the reported increase may be due, however, to improved detection or reporting techniques.

WILDFIRES THROUGH THE YEARS

Wildfires¹⁸ destroy thousands of acres of valuable grass and timberland each year. They also harm the environment, which takes years to recover. Wildlife and fish are killed, watersheds destroyed, topsoil eroded, and rivers are polluted with ash and silted with topsoil.

Some of the most disastrous fires in American history have been wildfires.¹⁹ The Peshtigo fire, Wisconsin, 1871, had losses involving 1,500 lives, an undetermined number of structures, and 1,280,000 acres of timberland; the Maine fire, 1947, with 16 lives, 1,200 structures, and 206,000 acres of timber and scenic forest land; the Cayote fire, California, 1964, with 1 life, 118 structures, and 67,000 acres of watershed lands; the Laguna fire, California, 1970, with 5 lives, 382 structures, and 175,000 acres of watershed lands; and most recently the Sycamore fire, 1977, Santa Barbara, California, with no lives, 250 structures, and 800 acres of watershed lands.

¹⁸ A wildfire is a fire in grass, brush, or timberland burning out of control. In the NFPA Uniform Coding for Fire Protection (901 Code), it is classified as an "outside fire."

¹⁹ Private communication from William R. Tikkala, Director, Cooperative Fire Protection, Forest Service, U.S. Department of Agriculture, Washington, DC, October 19, 1977.

Table 6. BUILDING FIRES OF DETECTED INCENDIARY OR SUSPICIOUS ORIGIN

Year	Total Number	Number per 100,000 Persons	Dollar Loss	Loss per Capita
1975	144,100	68	\$633,900,000	\$3.00

¹ These values are for the particular year indicated and are not five or ten year averages.

² States protect State and some privately owned lands within their boundaries.

SOURCE: Private communication, William R. Tikkala (Director, Cooperative Fire Protection, U.S. Department of Agriculture, Forest Service) to Philip S. Schaenman (NFFCA), October 19, 1977.

The majority of wildfires do not kill people or burn structures, but the threat is there. Most wildfires burn grass, brush, or timber land and result in lost or delayed production of forage for livestock, browse for wildlife, and trees for paper and timber. The forest and rangelands of the Nation where most wildfires occur are the responsibility of Federal and State fire protection agencies.

Wildland fires in forests and grasslands under Federal protection have been successfully reduced over the past 50 years. Statistics on these fires

for the years 1950 through 1975 are shown in Table 7. In 1950, the average fire on Federally-protected lands burned 285 acres before being brought under control; in 1976, it was only 33 acres. The number of fires has changed very little, although there are now many more acres under Federal protection.²⁰

The States protect 737 million acres of forest and non-forested watershed on State land and some privately-owned land within their bound-

²⁰ Statistics for 1977 may be vastly different due to several extremely large fires.

aries. This protection is usually provided through the State forestry organization by the State forester. Financial and technical assistance is provided to the States through the Clarke-McNary Act of 1924.

In 1976, the States reported 157,000 fires burning 2.1 million acres of protected land. In addition, the States estimated 69,000 fires burning 2.5 million acres on 101 million acres outside State fire protection jurisdiction. Statistics on wildfires for the years 1950 through 1976 are also shown in Table 7.

HOW THE UNITED STATES COMPARES TO OTHER NATIONS

It has often been reported that the United States has one of the worst fire records of any developed nation.^{21, 22} The different means of reporting and estimating numbers of fires in various countries make comparisons difficult. The most valid bases for comparison probably are the rates of *building* fires and deaths. A recent study by the Georgia Institute of Technology attempts to take into account reporting differences to the extent possible.²³ The study found that the U.S. rate of deaths resulting from building fires is indeed among the worst (Table 8).

This country's per capita dollar loss for building fires is also among the highest. As a fraction of the Gross National Product, per capita dollar loss is about average. However, the U.S. dollar loss per fire and the number of deaths per building fire are below the average of the 13 countries. The Georgia Tech study suggests that fire deaths and losses may be lower in other countries in part because they have devoted a greater part of their fire safety effort to prevention. The generally good U.S. job in suppression is not enough to offset our generally poor job in prevention, with the net

effect being higher death and injury rates than in other countries.

HOW FIRE COMPARES WITH OTHER HAZARDS

National policy should determine resources to be devoted to reducing hazards. Resource allocations should depend on the relative severity of various problems, the expected reductions relative to resources needed, and their effect on lifestyles and the public's feeling of security.

To put the fire problem in its proper perspective, fire losses must be compared to losses from other problems, such as crime, accidents, and natural disasters. Such comparisons are presented next, and they make it clear that fire is one of our major national problems.

Fires Versus Crimes, Accidents, and Natural Disasters

As shown in Table 9, fire causes far more loss of life and property damage than all natural disasters combined. Although fire is lower in life and dollar loss than crime or auto accidents, it is of the same scale as these two. Dollar loss estimates are difficult to compare because of differences in definition and selection of the types of costs included in estimation methodologies.²⁴

Fire vs. Residential Accident Deaths.—The more common causes of accidental residential deaths are ranked in Table 10. Fire is the second most frequent cause of accidental death in the home, after falls.

Fire vs. Other Catastrophes.—Fire has also been the cause of more catastrophic deaths in recent years than any other cause (Table 11). Some 27 percent of the deaths and 31 percent of the catastrophic incidents are from fires and explosions. Motor vehicle accidents follow with 23 percent of catastrophic deaths and 37 percent of incidents. Tornadoes, floods, hurricanes, and air transport accidents are next. All other causes for catastrophic incidents are of much less import.

U.S. Rank ⁴	11 of 13	9.5 of 13	14 of 15	14 of 15	2 of 13	7 of 15

¹ Only building fires were included in this comparison because differences in definitions and reporting in the systems used by various nations prevent valid comparisons of fire rates based on all fires. Although comparisons of building fires are the most valid, definitional differences arise even for this category. The data here, including those for the United States, are 1972-74 averages.

² Total fire deaths were used for comparisons because for the international data the percentage of the total which are building fire deaths in each country was not available.

³ German Federal Republic.

⁴ Lower rank indicates better performance.

SOURCE: Metropolitan Life Insurance Co., "Catastrophic Accidents, a 35-Year Review" *Statistical Bulletin*, March 1977, pp. 1-4. Basic data derived from news items in the daily press, reports of the National Weather Service, U.S. Bureau of Mines, and other sources. Data may be incomplete, particularly with regard to accidents taking five to nine lives.

Section IV

Selected Characteristics of Fires

This section presents an analysis of selected characteristics of the fire problem. It includes casualty characteristics, causes of residential and non-residential fires, comparisons among communities of varying sizes, statistics on when fires occur, and the performance of sprinkler systems. Results from the 1974 National Household Fire Survey of residential fires are also discussed. Part II of this report provides much greater detail. Data from 284,000 fire incident reports from the States of California and Ohio were used for this section.

The two States considered here have a combined population of almost 32 million persons, about 15 percent of the U.S. population. The data may or may not be typical of the entire Nation—we do not know yet—but they do cover communities of all sizes, many climates, and diverse geographical regions. Over 2,000 fire departments are represented.

This section illustrates the types of policy-relevant information that can be extracted from the National Fire Incident Reporting System (NFIRS). As more States enter the NFIRS system, the results will, of course, become more representative of the country as a whole.

In developing these results, we were faced with the difficulty of subdividing the fire problem into useful and understandable categories. Evaluations of the problem from many different perspectives aid in understanding its many facets. For example, to evaluate the effectiveness of prevention education, it is useful to distinguish fire causes related to human behavior from causes related to equipment failures. To evaluate prevention approaches dealing with making materials flame resistant, it is useful to group causes by "material first ignited." A major benefit resulting from the detail provided in the data collected by NFIRS is that

it permits analyses from these multiple, but necessary perspectives.

The approach taken for the analysis presented in this section is that it must be useful to State and local fire services, especially those officials concerned with fire prevention policy. Many of the analyses are also likely to be of interest to the Federal Government, industry, or researchers. The detailed breakdowns can also be regrouped according to other viewpoints; for example, information on fires involving consumer products can be gleaned from the analyses of heating, cooking, and other types of fires in Part II.

INJURIES CAUSED BY FIRE

The most important aspect of fire protection is personal safety. To reduce casualties, it is important to know what types of injuries occur, where and why they occur, and who is being hurt. Table 12 summarizes the types of injuries and causes of deaths sustained by civilians and firefighters in Ohio in 1976. (More details and data for other States and cities are given in Part II, pages 57 through 149.)

Injuries to firefighters account for over half (56 percent) of all injuries associated with fires attended by the fire service in Ohio. Although there is some question on the extent to which minor injuries to both firefighters and civilians are reported, firefighters clearly account for a substantial portion of the total injuries from fire in Ohio and many other places. Thus, injuries to firefighters require special attention if we are to make a major reduction in overall fire injuries and reduce the exceptional risks run by firefighters.

Smoke inhalation is the most common injury to firefighters in Ohio (25 percent), followed by

Table 12. FIRE CASUALTIES BY NATURE OF INJURY—Ohio (NFIRS 1976)

Total	224	100%	136	100%	88	99%

¹ Includes heart attacks and strokes.

² The nature of injury resulting in a firefighter fatality is not indicated because in 1976 in Ohio there were only five firefighter fatalities reported to NFIRS.

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than two were rounded to the nearest tenth of a percent.

SOURCE: Ohio 1976 NFIRS data. Estimated completeness is roughly 50 percent (Reference 11).

strains or sprains (17 percent), and cuts or wounds (17 percent).

Firefighter deaths in Ohio were too few (5 were reported) to make any generalizations. However, as previously mentioned, a recent IAFF study shows that almost 45 percent of on-duty firefighter deaths nationwide are due to heart attack, more than three times the second largest cause of death.²⁵

In Ohio, males account for 61 percent of the civilian deaths and 65 percent of the civilian injuries, similar to the totals for the United States as a whole (Figure 2, page 17).

²⁵ Balanoff, Thomas, *Fire Fighter Mortality Report* (Washington, DC: The International Association of Fire Fighters for the National Fire Prevention and Control Administration and the Center for Fire Research, Institute for Applied Technology, National Bureau of Standards, May 1976), Contract No. 4-35909, p. 111.

The vast majority of civilian casualties in Ohio were due to burns or smoke inhalation—83 percent of injuries and 79 percent of fatalities. The most frequent injury is burns alone (43 percent); the most frequent fatality is from burns and smoke together (55 percent).

WHERE FIRE LOSSES OCCUR

Shown in Table 13 is the relative distribution of California and Ohio fires and fire losses among the major occupancies. The non-residential category is further subdivided into structures, mobile property, and outside property. Mobile homes have been included with residences.

About half of all fires in the two States occur on outside property, such as grass, trees, brush, or rubbish. These are usually small fires which do

**Table 13. REPORTED FIRE LOSSES FOR MAJOR OCCUPANCY TYPES¹—
California (CFIRS 1975), Ohio (NFIRS 1976) Combined**

Occupancy Type	Fires		Deaths		Injuries		Dollar Loss	
	Number	Percent	Number	Percent	Number	Percent	(Thousands)	Percent
Residential ²	63,555	22	471	68	5,093	57	\$155,609	44
Non-residential Structure	29,275	10	48	7	2,329	26	150,884	43
Mobile Property	43,037	15	148	21 ³	767	9	24,732	7
Outside Property (Rubbish, wildlands, etc.)	148,112	52	28	4	751	8	22,183	6
Total	283,979	99%	695	100%	8,940	100%	\$353,408	100%

¹ Reported fire incidents shown do not include all fires attended by fire departments, only those reported to the State (mostly by the fire service). Estimated completeness is on the order of 90 percent for California and 50 percent for Ohio (Reference 11).

² Mobile homes are included in this category and excluded from the Mobile Property category.

³ This percent is higher than the national average. Possible reasons are that Californians drive more or different definitions are used in data collection.

not result in significant losses, though they include some large, dangerous wildland fires.

Apart from these outside fires, residential fires are the principal category of fires and fire losses. More specifically:

Fire Incidents—Residential fires comprised slightly over two-thirds of the structural fires in the two States (and 22 percent of all fires.)

Deaths —Residential fires accounted for 68 percent of deaths; mobile property fires (mostly automobiles) were second with 21 percent. Non-residential structural fires—which include public places such as nightclubs, schools, and stores—accounted for only 7 percent of deaths.

Injuries —Residential fires accounted for 57 percent of injuries; non-residential structural fires were second with 26 percent.

Dollar Loss —Residential and non-residential structural fires accounted for about the same dollar loss, approximately 43 percent each.

Clearly the residential fire problem must receive a high priority if the United States is to achieve a significant reduction in human and economic fire losses.

VIEWING FIRE CAUSES

There are many ways to describe the cause of a fire and to group similar causes in a way that helps in making fire protection decisions. We decided to use the cause categories shown in Table 14 as shorthand for more complex causal factors. How we arrived at that choice is discussed below.

The NFPA 901 Coding System, upon which the National Fire Incident Reporting System is based, does not give a single "cause of the fire," but, rather, it gives a more detailed breakdown that corresponds to the physical environment and contributing factors of cause. An ignition requires three basic ingredients: a source of heat, something to ignite, and a triggering mechanism or agent to bring the two together. The corresponding NFPA 901 data elements are formally called: form of heat of ignition, type of material ignited, and ignition factor. Other 901 data elements cover equipment involved in ignition and form (or usage) of material ignited. These five factors together comprise the cause. By using these factors, one can analyze the causes of fires from several different prevention perspectives, such as human behavior or flammability of materials, as appropriate. One of the major advantages of the NFIRS system is that it collects data on each individual element so that they can be aggregated for analytical purposes into different groups at different times as required.

Viewing the relative frequency of incidents, casualties, or dollar losses separately for each of

Table 14. "CAUSE" CATEGORIES USED IN THIS REPORT

Sorting Sequence	"Cause" Category ¹	Definition
1	Exposure	Caused by heat spreading from another hostile fire.
2	Natural Source	Caused by sun's heat, spontaneous ignition, or chemical, lightning, or static discharge.
3	Incendiary/Suspicious	Fire deliberately set or suspicious circumstances.
4	Explosives, Fireworks	Self-evident; explosives used as incendiary devices included in category 3.
5	Smoking	Cigarettes, cigars, pipes as heat of ignition.
6	Children Playing	Includes all fires caused by children playing with any materials contained in the categories below.
7	Heating Systems	Includes central heating, fixed and portable local heating units, fireplaces and chimneys, water heaters as source of heat.
8	Cooking Equipment	Includes stoves, ovens, fixed and portable warming units, deep fat fryers, open fired grills as source of heat.
9	Air Conditioning, Refrigeration	Includes dehumidifiers and water cooling devices as well as all air conditioning and refrigeration equipment as source of heat.
10	Electrical Distribution	Includes wiring, transformers, meter boxes, power switching gear, outlets, cords, plugs, lighting fixtures as source of heat.
11	Appliances	Includes TV's, radios, phonographs, dryers, washing machines, vacuum cleaners, separate motors, hand tools, electric blankets, irons, electric razors, can openers as heat source.
12	Gas	Material first ignited was a gas: natural, LP, manufactured, anesthetic, acetylene, other gas.
13	Flammable, Combustible Liquid ²	Material first ignited was flammable liquid: gasoline, ethyl alcohol, ethyl ether, acetone, jet fuel, turpentine, kerosene, diesel fuel, cooking oil, lubricating oil, etc.
14	Open Flame, Spark (Heat from)	Includes torches, candles, matches, lighters, open fire, back-fire from internal combustion engine as source of heat.
15	Other Equipment	Includes special equipment (radar, X-ray, computer, telephone, transmitters, vending machine, office machine, pumps, printing press), processing equipment (furnace, kiln, other industrial machines), service, maintenance equipment (incinerator, elevator).
16	Other Heat	Includes all other fires caused by heat from fuel-powered objects, heat from electrical equipment arcing or overloaded, and heat from hot objects not covered by above groups.
17	Unknown	Cause of fire undetermined or not reported.

¹ "Cause" as used here is a shorthand notation for what is sometimes a complex chain of events leading to a fire.

² Note that incendiary fires involving flammable liquids are covered in category 3, not 13.

the above five NFPA 901 Ignition Characteristics provides insights into some of the most important components of the fire problem. This is one of the most common types of analysis used by the fire service today. One of the things it can be used to show, for example, is how often specific materials (such as plastics or wood) or products (such as mattresses) are involved in ignitions. Other examples are shown in Appendix VII.

While viewing the data from a single causal factor provides useful information, it is frequently desirable to consider several factors to understand their joint effect, or the "scenario" in which they all played a role. Table 15 shows the relative frequency of death and amount of dollar loss for the top five scenarios of Ohio residential fires. The four factors used for each scenario make up a chain of events which led to the fires. A variety of proposed intervention strategies can be evaluated to determine if any could break that chain and prevent the fire from occurring. The scenario method is an example of aggregating several NFIRS (901) data elements for analytical purposes.

Scenario analysis has several drawbacks when only limited data are available. One arises from spreading a small number of fire incidents over many categories. Frequently a situation results where even the most frequent pattern, or scenario, may appear "trivial" because it accounts for a small percentage of the fires. A related drawback is that a major phenomenon may be masked

by being broken into too many little categories. For example, Table 15 distributes fires involving smoking materials that ignite textiles into three scenarios. Other fires involving smoking materials are distributed among many additional scenarios. Smoking, therefore, appears in this table to be a smaller problem than it really is.

To obtain a general overview of the fire problem, it seemed more advantageous to use the aggregated cause categories shown in Table 14.²⁶ For most fires there is no problem in choosing an appropriate category. However, there are some instances when more than one cause category could be used to describe the same fire incident. For example, one person might describe a fire resulting from children playing with a stove as a "children playing" fire while another person would describe it as a "cooking-related" fire. Rather than assign multiple causes to the same fire—in which case the sum would exceed the total number of fires—we have used a hierarchical approach (sorting sequence) which assigns a single cause category to each fire.

The basic idea in the hierarchical ranking of the categories is that a fire is compared against the first category; if it fits, it is assigned to that cause category. If not, it is checked to see if it fits in the second category, etc. For example, a

²⁶ This table is also repeated inside the back cover for easy reference. For the reasons given in the text above, those individuals using NFIRS Standard Feedback Reports should note that their reports are not directly comparable with the Tables presented in this volume.

Table 15. EXAMPLE "SCENARIO" DESCRIPTIONS OF RESIDENTIAL FIRES—Ohio (NFIRS 1976)

<i>The Top Scenarios for Deaths in Residential Fires</i>		Percent of Deaths
1. Day/Smoking materials/Textile/Furniture. (e.g., cigarette left on upholstered furniture during the day)		3.9%
2. Night/Smoking materials/Textile/Furniture.		3.9
3. Night/Smoking materials/Textile/Bedding or clothing. (e.g., cigarette dropped on bed at night)		3.9
4. Night/Hot object/Textile/Bedding or clothing.		3.0
5. Night/Smoking materials/Natural products/Furniture.		3.0
<i>The Top Scenarios for Dollar Loss in Residential Fires</i>		Percent of Dollar Loss
1. Night/Arc from electric equipment/Wood/Structure or finish.		5.2%
2. Day/Arc from electric equipment/Wood/Structure or finish.		3.8
3. Night/Smoking materials/Textile/Furniture.		1.8
4. Day/Smoking materials/Textile/Furniture.		1.7
5. Day/Open flame/Textile/Bedding or clothing.		1.4

¹ Each scenario is made up of the following sequence of elements: Time of Day/Source of Heat/Material First Ignited/Form of Material First Ignited. Incidents with an unknown value for any element are excluded from the calculation of percentages as well as from the list of top scenarios.

fire unintentionally set by a child playing with gasoline near a stove would be categorized as "children-playing," not as "flammable liquid," and not as "cooking." This approach can be somewhat misleading in that the categories at the beginning of the list are "favored" and tend to appear larger with respect to those at the end of the list than they would under a different hierarchical ranking. For example, if the category "open flame, spark" was placed earlier in the list than "incendiary/suspicious," many fires currently contained in the "incendiary/suspicious" category would switch categories, the relative frequencies would alter, and a different view of the fire problem would result. Another major problem with such categorization schemes is that fires involving a particular material first ignited are scattered across categories and require separate analysis.

Another element of arbitrariness that enters into the simplified cause categories, especially when equipment is involved, concerns the specific types of equipment to be included. For example, if water heaters or fireplaces were separated out from the heating category, this category would appear less important relative to other categories.

Certainly, the approach described in Table 14 cannot serve all purposes. The categories of that table are not in order of importance, but rather the order in which we felt it logical to make meaningful categorizations for guiding prevention efforts. A variety of cause categories have been used for analytical purposes and presentation by different organizations and fire departments. Our selection was a compromise.

CAUSES OF RESIDENTIAL FIRES

The "causes" of residential fires and how they vary by size of community are discussed here. The analysis in this and the next section is based on fires reported to the fire service. The third section discusses the cause of fires not reported to the fire service.

Figure 13 shows the relative frequency of the different causes of residential fires. There are eight major cause categories for fires in residences: cooking, smoking, heating, incendiary/suspicious, electrical distribution, appliances, children playing, and open flames or sparks. These eight do not have the same rank order in both States, but they are the top eight in each State. For example, fires involving "open flames

or sparks" is a high-ranking major cause for California, but is a lower ranked cause for Ohio; the reverse is true for children playing. These eight categories account for at least 80 percent of all residential fires, at least 64 percent of all residential fire deaths, at least 77 percent of all residential fire injuries, and at least 62 percent of residential dollar losses.²⁷ A more detailed description of leading causes follows:

Fire Incidents— The top four major cause categories — cooking, smoking, heating, and incendiary/suspicious — represent the principal causes of reported fires and account for 55 percent of them.

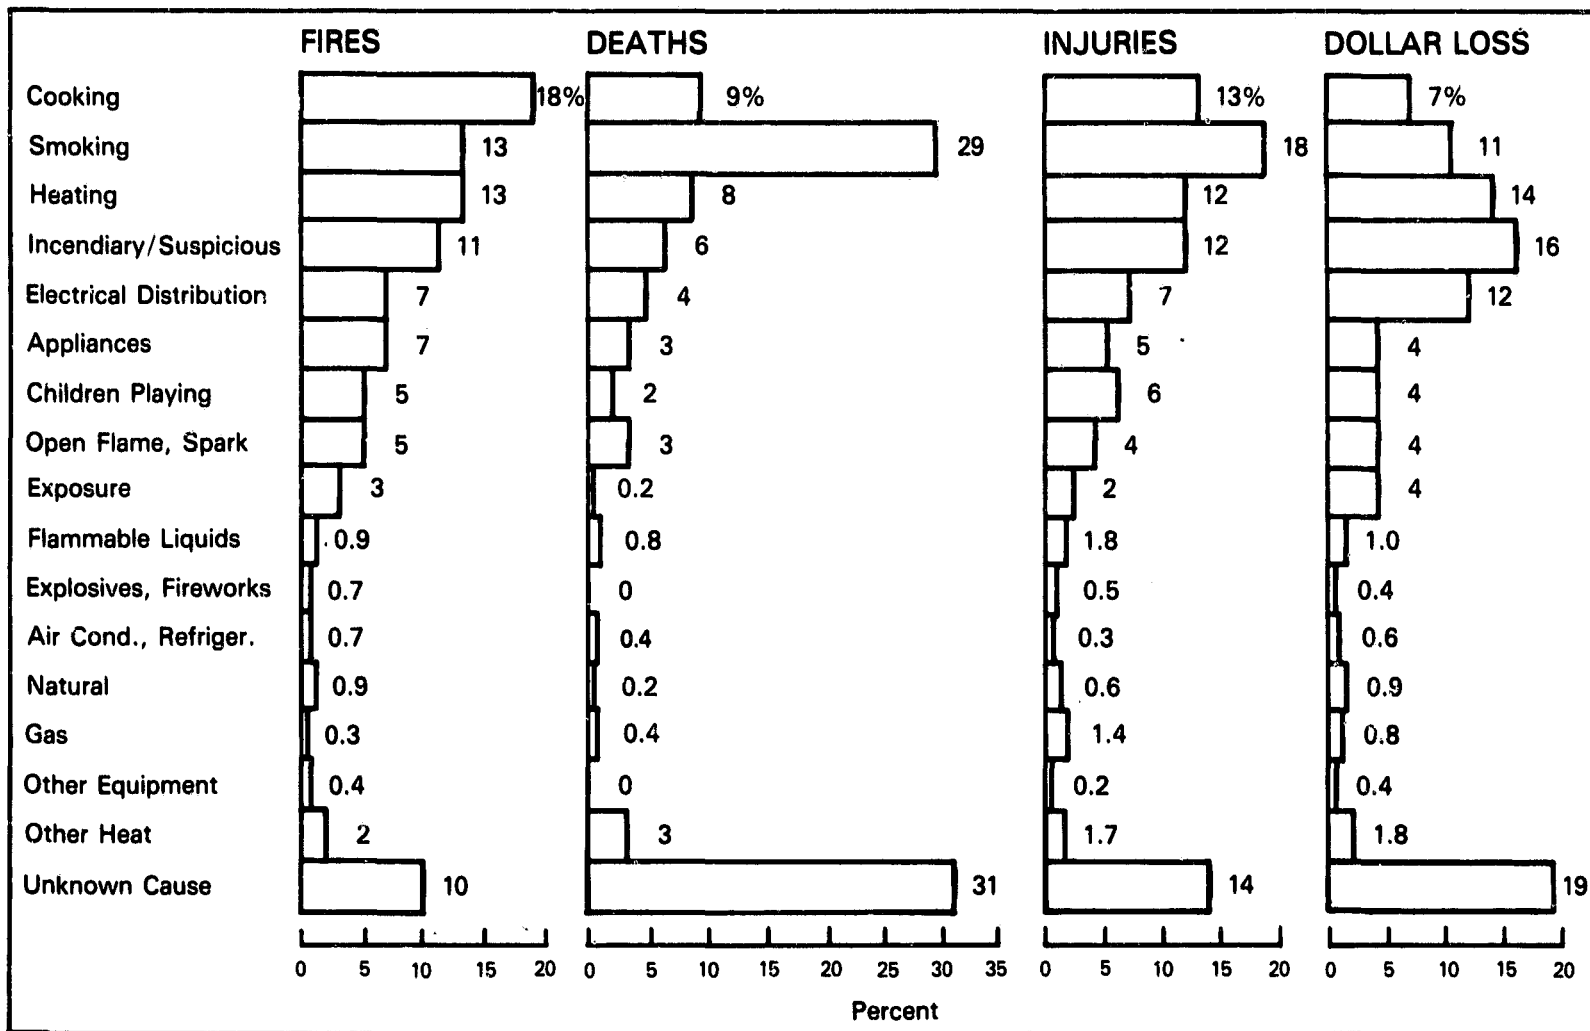

Deaths — Fires resulting from people smoking is by far the principal known cause of fire death (29 percent), with cooking and heating next. The largest category is actually "unknown cause," which applies to 31 percent of the deaths.

Injuries — The top four causes—cooking, smoking, heating, incendiary/suspicious — account for 55 percent of all injuries.

Dollar Loss — Fires of incendiary/suspicious nature result in the most dollar loss, followed by heating, electrical distribution, and smoking fires. Note that electrical distribution fires cause almost double the dollar loss of fires involving cooking, even though cooking fires are more than twice as frequent. Again, the unknown category contains the largest proportion; many of these may well be of incendiary origin.

²⁷ To the extent that the fires currently classified as being of unknown cause were actually caused by any of these eight causes, the hazard presented by these causes would be greater than shown.

**Figure 13. CAUSES OF REPORTED RESIDENTIAL FIRES —
California (CFIRS 1975), Ohio (NFIRS 1976) Combined¹**

¹ Based on approximately 64,000 residential fires in California and Ohio. These were fires attended by the fire service and comprised roughly 90 percent of such fires in California and 50 percent in Ohio (Reference 11).

What can be done about the residential fire problem? Some actions that households may take to prevent the leading causes of fires are listed in Table 16. Smoke detectors, coupled with a practical escape plan, can reduce casualties and losses once fire does strike. The fire service (and others) may wish to teach these preventive actions to the public along with providing data to motivate them to take the required action.

FIRE CAUSES IN DIFFERENT SIZE COMMUNITIES

There is considerable variation in fire rates and losses between California and Ohio, and also among cities within each of these States. Large differences in fire loss among cities of varying population size were mentioned earlier in the discussion of data from the 1974 NFPA survey (page 18). Similar differences are found when considering residential fires alone. A better understanding of the reasons for such diversity may be gained by examining variations in fire rates among different sized communities for each of the major causes of residential fires. Figure 14 illustrates the average fire rate for the Ohio cities by population group for each of the eight major cause categories.

The Ohio cities were grouped into four ranges of population: over 200,000 persons, 50,000 to 200,000 persons, 25,000 to 50,000 persons, and less than 25,000 persons. The last group included rural communities as well as small towns. Data from seven cities using the NFPA 901 codes under the Uniform Fire Incident Reporting System (UFIRS) were also included in the comparison.^{20, 29} The UFIRS cities provide a fifth group. The fire rate for each of the five groups is plotted in Figure 14 at the mean value of the population range.

The largest differences in fire rates among cities occurred in cause categories dominated by human carelessness or misbehavior—such as smoking or arson, rather than in categories where equipment malfunctions dominate—such as appliances, electrical distribution, and heating. Several interesting points are suggested by this data. First, although the larger Ohio cities probably had more complete reporting than the

smaller cities,³⁰ the differences in fire rates appear to be larger than would result just from differences in reporting completeness. This tends to be supported by the constancy of the equipment-related causes with population—equipment of the same quality tends to be sold all over, whereas socioeconomic mixes and behavior of citizens may vary considerably from large cities to rural areas.

Second, if the differences are indeed real and not data artifacts, they point up the potential for reducing fires caused by carelessness and other "human behavior" problems—citizens in some communities outperform those in others five to one. While the circumstances they face may be vastly different, figuring out how to move the worst rates even part way toward the best rates could have a significant impact on the fire problem. (Determining how to induce the changes is the focus of NFPCA's Public Education Office.)

Third, cities should compare their performance by fire cause to others in their population class. Further detailed analysis of causes by socioeconomic classes within a city should provide information that is important in targeting public education programs more effectively. Several recent studies relate community characteristics to fire rates.^{31, 32, 33, 34}

Finally, a note of caution about data for rural areas. The profile here for that class does not agree with that from the NFPA survey data presented earlier. Here it is a low rate; there it is a high rate. Although precision and accuracy are lowest for data from the rural communities, we do not know if this is why the profiles differ or if the differences are real.

Table 16. ACTIONS TO PREVENT FIRE IN THE HOME¹

Smoking Fires

1. Don't smoke in bed, especially after drinking alcoholic beverages.
2. Develop the habit of checking for cigarettes under chair cushions before going to bed, after people have been smoking near upholstered furniture.
3. Use safety ashtrays—the type which causes a lit cigarette to fall into the ashtray, not out of it.
4. Leave ashtrays to empty in the morning, to avoid throwing live cigarette butts in with ignitable trash.

Cooking Fires

1. Stay around and pay attention once you have started cooking. Unattended cooking is one of the most common causes of fires.
2. Clean grease from the stove and flue.
3. Keep combustibles—such as curtains or drapes, clothing, packaged foods, and trash—away from stoves.

Heating Fires

1. Have your heater or heating system checked by a competent service man at least once a year.
2. Take special care with fireplaces. Use a spark screen to prevent sparks from flying, and be sure the chimney is unblocked and without too much soot accumulation. Fireplace fires are very common, even in California.
3. Keep combustibles (dust mops, cleaning fluids, aerosols, Christmas decorations, etc.) at least 18 inches away from all heating units.

Electrical Distribution Fires

1. If there is any sign of electrical trouble, shut off power to the circuit and have it checked by a good electrician.
2. Check cords and plugs frequently for signs of broken insulation or frayed wires.

Appliance Fires

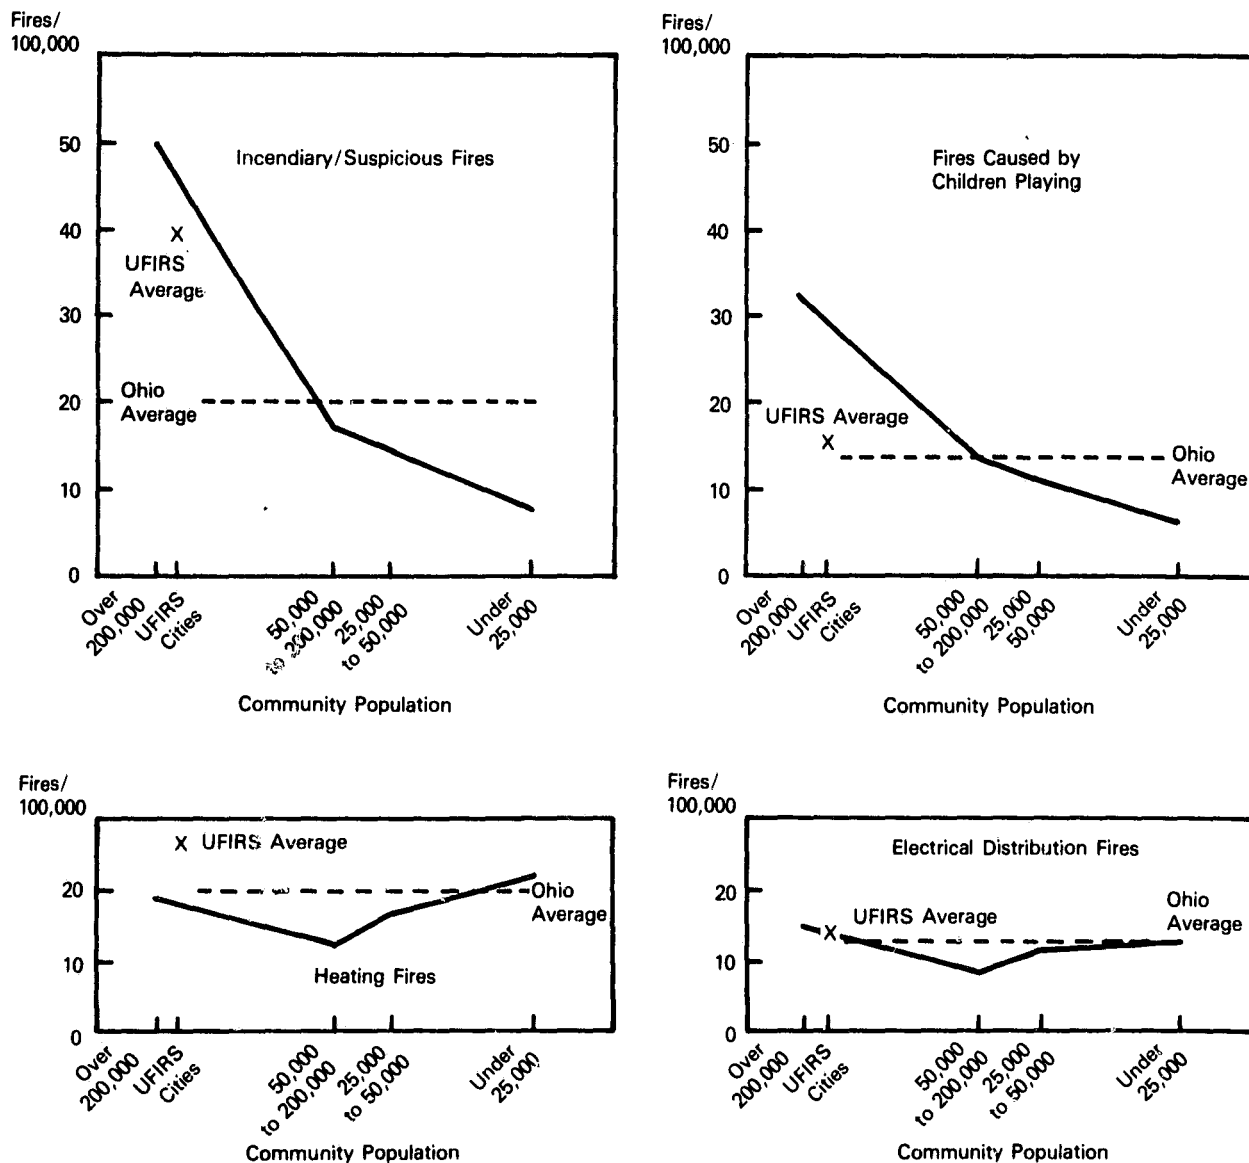

1. Don't overload dryers, and be sure to remove lint regularly.
2. Check your appliances at least once a year to see that they are clean and functioning properly, and that insulation has not broken or cracked.
3. Buy appliances having Underwriters Laboratories or other nationally recognized testing laboratory approval.

Fires Caused by Children Playing or Intentionally Setting Fires

1. Keep matches and cigarette lighters away from children (and senile adults, for that matter).
2. Suggest professional counseling to help children work out problems which motivate fire setting.

UNREPORTED HOUSEHOLD FIRES

Most household fires are not reported to the fire service. These fires are fought and extinguished by the householder, perhaps assisted by neighbors, or they may simply go out by themselves. An understanding of the total fire problem would be incomplete if these fires were ignored, especially since many cause nontrivial injuries and losses.

Under the sponsorship of the National Bureau of Standards and the Consumer Product Safety Commission, the Bureau of the Census conducted a "national household fire survey" of 33,000 households in 1974. These households identified a total of 2,463 fires experienced between April 1973 and April 1974 in residences, yards, autos, garages, boats, etc. A detailed analysis of this survey was completed recently for the National Fire Administration.³⁵ A consumer-product-oriented analysis by the CPSC has also been prepared.³⁶

Some of the highlights of the survey are:

- Less than 9 percent of household fires are actually reported to the fire service.
- Two percent of all fires resulted in loss of one or more days of work; only 57 percent of these were reported fires. That is, almost half of the fires resulting in time lost from work were *not* reported.
- About 15 percent of all fires resulted in one or more injuries or had an estimated damage greater than \$200; almost half of these fires were not reported. Of these significant loss fires 15 percent were fires where food or grease was the first item ignited; 91 percent of these food or grease fires were not reported to the fire department. Of the other 85 percent significant loss fires, 50 percent were not reported.
- Five percent of all fires start when no one is home.
- Eighty-two percent of all building fires damaged only contents; that is, did not involve fire, smoke, or water damage to the walls, floor, or ceiling of any room.

- Fifty-five percent of all building fires involving some room damage were in the kitchen.
- Fifty percent of all building fires had only smoke damage and no flame or water damage.
- Five percent of all building fires involved exterior walls; 44 percent of these fires were to buildings having wood siding.
- Less than 0.3 percent of all building fires spread to another building.
- Eighty-three percent of all fires occurred during waking hours—7 a.m. to 10 p.m.
- Forty-seven percent of all fires involved cooking; 3 percent of these cooking fires were reported.
- Twenty-nine percent of all fires involved grease.
- Excluding those fires of unknown location, 65 percent of all fires occurred in the kitchen (53 percent if fires of unknown location are included), 4 percent of these were reported.
- Fifty percent of all fires were extinguished by females of the household, 30 percent by males of the household, and 8 percent by fire departments (others extinguished the remainder).

The Household Survey also yielded information on injuries from fires. Although the results should be considered tentative because they are based on only 138 injuries distributed across many categories, the principal findings are shown in Table 17. Briefly:

- In all fires, males sustained 60 percent more injuries than females.
- Males had four times more injuries from non-household fires than females (this seems to be the principal reason for the male and female injury differences).
- Females sustained 50 percent more injuries from household fires than males.
- Fires from cooking caused 43 percent of the injuries in household fires; trying to put out a (non-cooking) fire caused 17 percent of household injuries.

The University of Wisconsin analysis also showed that household members had a major problem in recalling fires. Survey respondents apparently failed to mention many fires that occurred during the months about which they were asked. In fact, it was estimated that only

NOTE: Some column totals may not equal the sum of the elements due to round-off error.

about 40 percent of the total fires that had occurred within 12 months prior to the interview were actually reported during the interview. Most of those omitted are believed to be minor fires, for example, grease fires, but many may have been nontrivial.

Making allowance for unrecalled fires, the estimate of the total number of annual household fires in the country comes to about 13 million, or nearly one incident per year for every five households.

CHARACTERISTICS OF NON-RESIDENTIAL STRUCTURE FIRES

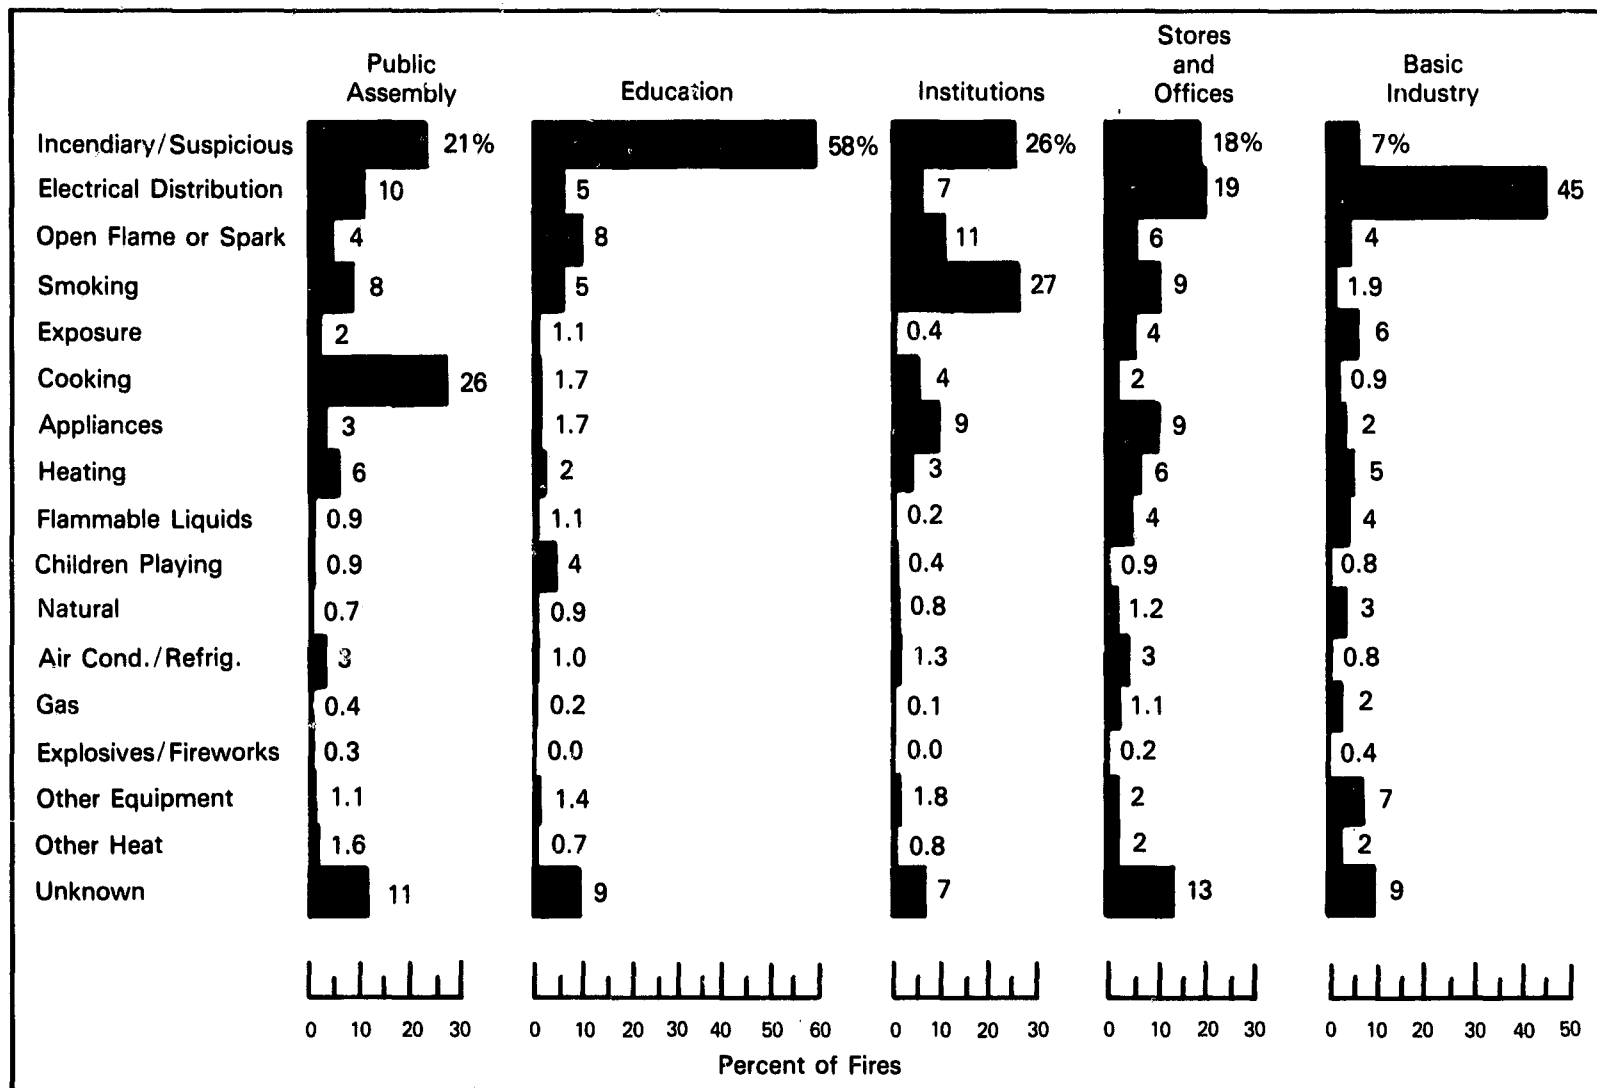

The causes of fires in non-residential structures are discussed in this section. Figure 15 shows the relative frequency of the different causes of fires reported in non-residential structures in Ohio and California. Fires of incendiary or suspicious origin, the most frequent cause, accounted for 27 percent of all reported non-residential structure fires, 21 percent of the deaths, 19 percent of the injuries, and 27 percent of the dollar loss. A variety of causes are second, depending upon which loss measure is used. Flammable liquids rank second in deaths; while natural causes (lightning or spontaneous ignition) are important in injuries, and heating, for dollar loss. Fires with unknown cause are actually second most frequent after incendiary/suspicious.

Table 18 shows causes of non-residential fires by occupancy type. The values across the bottom of the table give the totals of fires, deaths, injuries, and dollar losses. The entries in the table represent, for each occupancy, the percent of fires attributable to each cause. There appear to be strikingly different patterns of losses and causes for each occupancy type. The three occupancies showing the greatest dollar losses are storage, stores and offices, and manufacturing.

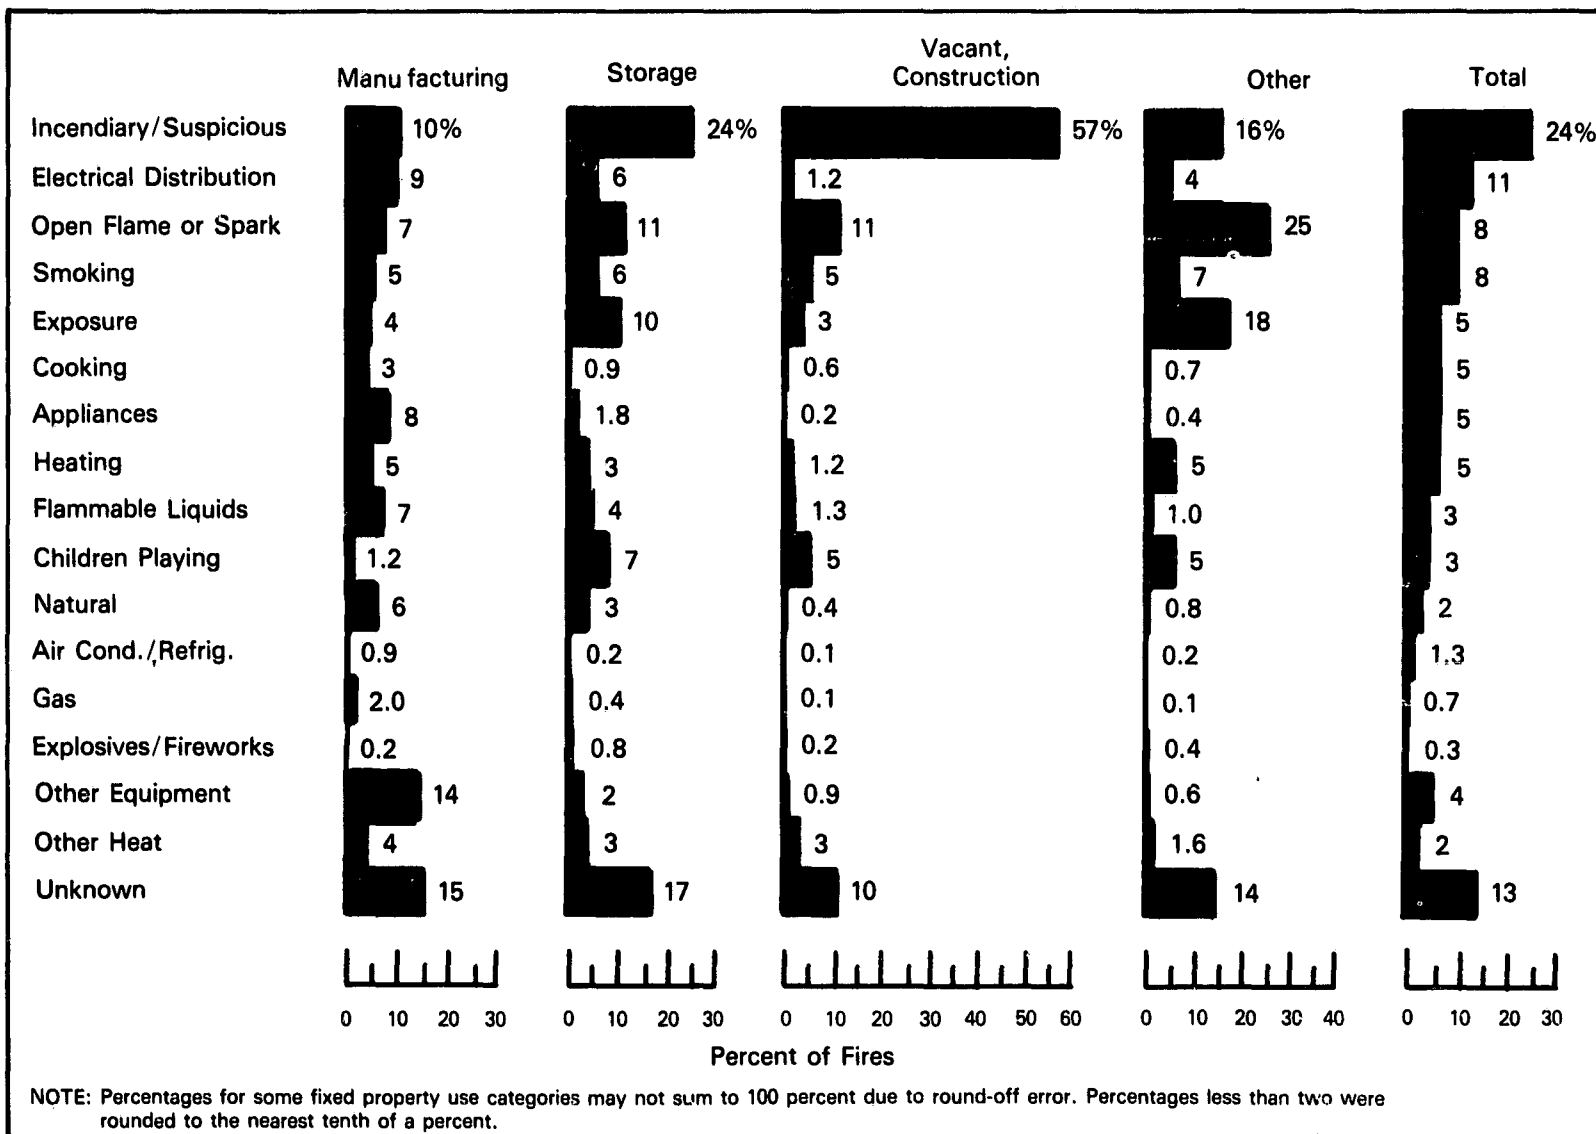

The fire losses shown in the table for industry and manufacturing are probably less than half of the actual total. Since many large businesses and industries maintain their own fire brigades, only a small proportion of their total fires may be reported to local fire departments. Though we may not know the full extent of the fire problem in these properties, the part involving public fire departments is included in the reported data; the unknown part is that which the companies are handling themselves.

To help pinpoint problems on which to focus and to measure success those interested in fire prevention can array the data from their own communities in a manner similar to Table 18. For example, the table illustrates that in these two States most fires in schools are incendiary and relatively few in schools are from smoking. Cooking fires are the most common cause in public assembly properties, particularly in restaurants (as can be seen in the data presented in

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than two were rounded to the nearest tenth of a percent.

Part II). Electrical distribution problems were by far the most prevalent cause of fires in basic industry. These are problems that prevention programs should focus on.

Table 19 lists some potential ways to reduce the leading non-residential fire problems. They are simplified summaries of some complex fire prevention programs. In addition, public buildings likely to be occupied by large groups should be sprinklered, have adequate fire and smoke barriers, and have adequate exits that are properly

marked. Data on the magnitude of the problems in different occupancy types may not only assist in targeting these prevention efforts, but also may be used to help persuade businesses and institutions to cooperate. For example, telling a California restaurateur that there were 738 cooking-related fires in restaurants in his State, and that they caused 23 injuries and \$1,216,000 property damage, might move him to act more quickly than simply arguing in a general way that it's in his "best interest."

**Table 19. SOME WAYS TO PREVENT
NON-RESIDENTIAL FIRES**

Incendiary and Suspicious Fires

1. Ensure that suspicious fires are thoroughly investigated.
2. Make thorough fire prevention inspections of property subject to incendiary fires.
3. Make property secure against intrusion and provide increased surveillance.

Smoking Fires

1. Make sure institutional patients smoke only in safe areas and, if necessary, only when supervised.
2. Enforce "no smoking" regulations in stores, offices, and storage properties.

Cooking Fires (in places of public assembly)

1. Keep stoves and especially grease flues clean. Where practical, install fixed extinguishing systems in exhaust hoods and grease flues.
2. Make sure grease flues meet appropriate codes.

Electrical Distribution Fires

1. Make electrical distribution equipment a prime point of attention when making fire prevention inspections.

Open Flame and Spark Fires

1. Make sure open flames are properly guarded.
2. Set up a permit system for cutting and welding operations, and have a competent fire guard standing by.

Fires Caused by Children Playing (in storage areas)

1. Make storage buildings and areas secure.
2. Remove trash, and cover easily ignited stock.

¹ This represents a simplified summary of some quite complex fire prevention programs.

CHARACTERISTICS OF MOBILE AND OUTSIDE PROPERTY FIRES

Table 20 presents the fire losses from mobile and outside occupancies. Automobiles are, of course, the principal mobile category. Automobile fires account for 75 percent of the fires, 46 percent of the deaths, 56 percent of the injuries, and 49 percent of the dollar loss in the mobile property category.

Most outside fires involve either refuse or trees/grass/brush. Forest and other wildland fires usually occur in remote areas, away from municipalities.³⁷ Many of these fires are not reported to fire departments; therefore, the totals for wildfires in Table 20 may be low.³⁸

FIRE LOSSES BY DAY, WEEK, AND YEAR

Fires, fire deaths, and fire injuries are spread unevenly over the day, week, and year. Figures 16 (all occupancies) and 17 (residential only) show that most Ohio fires reported to the fire service occur in the afternoon and early evening. But fire deaths peak in the late evening and early

morning hours (11 p.m. to 4 a.m.), the time when most people are asleep. One reason for the large number of fire deaths in these hours might be that sleep is usually deepest when a person first falls asleep.

Injuries show two peaks, during the early evening and early morning hours. Perhaps the first peak is for fires in which people are involved in an activity that is associated with fire (for example, cooking), and the second peak may represent fires that occur while people are asleep, but through some good fortune, they escape only with injuries.

Fire deaths are slightly more frequent on a weekend day than a weekday, but the pattern is not pronounced in these two States (see Figure 18). Wednesday is almost as bad for deaths as Sunday. Fire injuries and losses also fail to show a pronounced clustering.

Fire deaths in Ohio show clustering about the beginning of the year (Figure 19), but injuries and losses exhibit only slight fluctuations. The number of Ohio fires peak in April and November.³⁹

Local governments should analyze their own data to see what times of the year, days of the

³⁷ There are, of course, spectacular exceptions such as the 1977 Santa Barbara wildfire which consumed hundreds of homes.

³⁸ The U.S. Department of Agriculture publishes a variety of statistics on wildfires: See page for summary statistics.

³⁹ Toledo, for example, reports a large number of grass and brush fires in April, especially when there is a shortage of rain, and a large number of leaf fires in November—certain companies go from one separate incident to another.

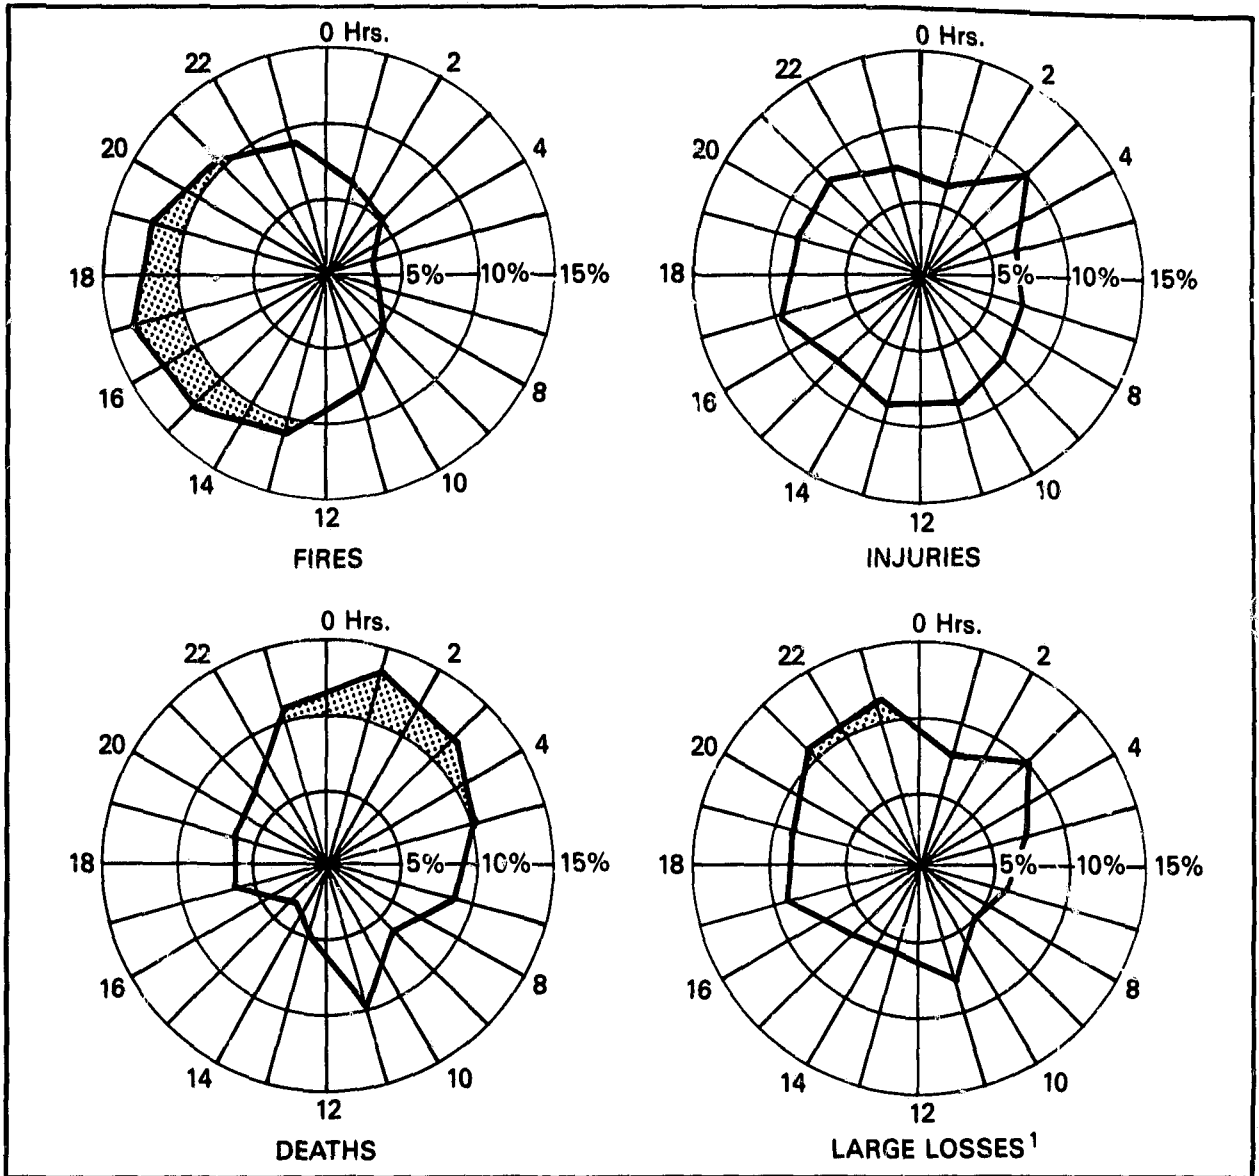

Table 20. SUMMARY OF REPORTED MOBILE AND OUTSIDE LOSSES—California (CFIRS 1975) and Ohio (NFIRS 1976) Combined

Property Type	Fires		Deaths		Injuries		Dollar Loss	
	Number	Percent	Number	Percent	Number	Percent	(In Thousands)	Percent

week, and times of day have peak incidence and losses. The pattern of fires may vary a great deal from one community to the next.

PERFORMANCE OF FIRE PROTECTION EQUIPMENT

Two of the most effective ways in which technology can be used to reduce human and property losses from fire involvement are smoke detectors and automatic sprinklers.

Smoke Detector Performance

One encouraging recent trend has been the purchase of home smoke detectors by many families. It is estimated that about 10,000,000 units were sold in 1977.⁴⁰ With some 4,000,000 in use before then, many millions of households

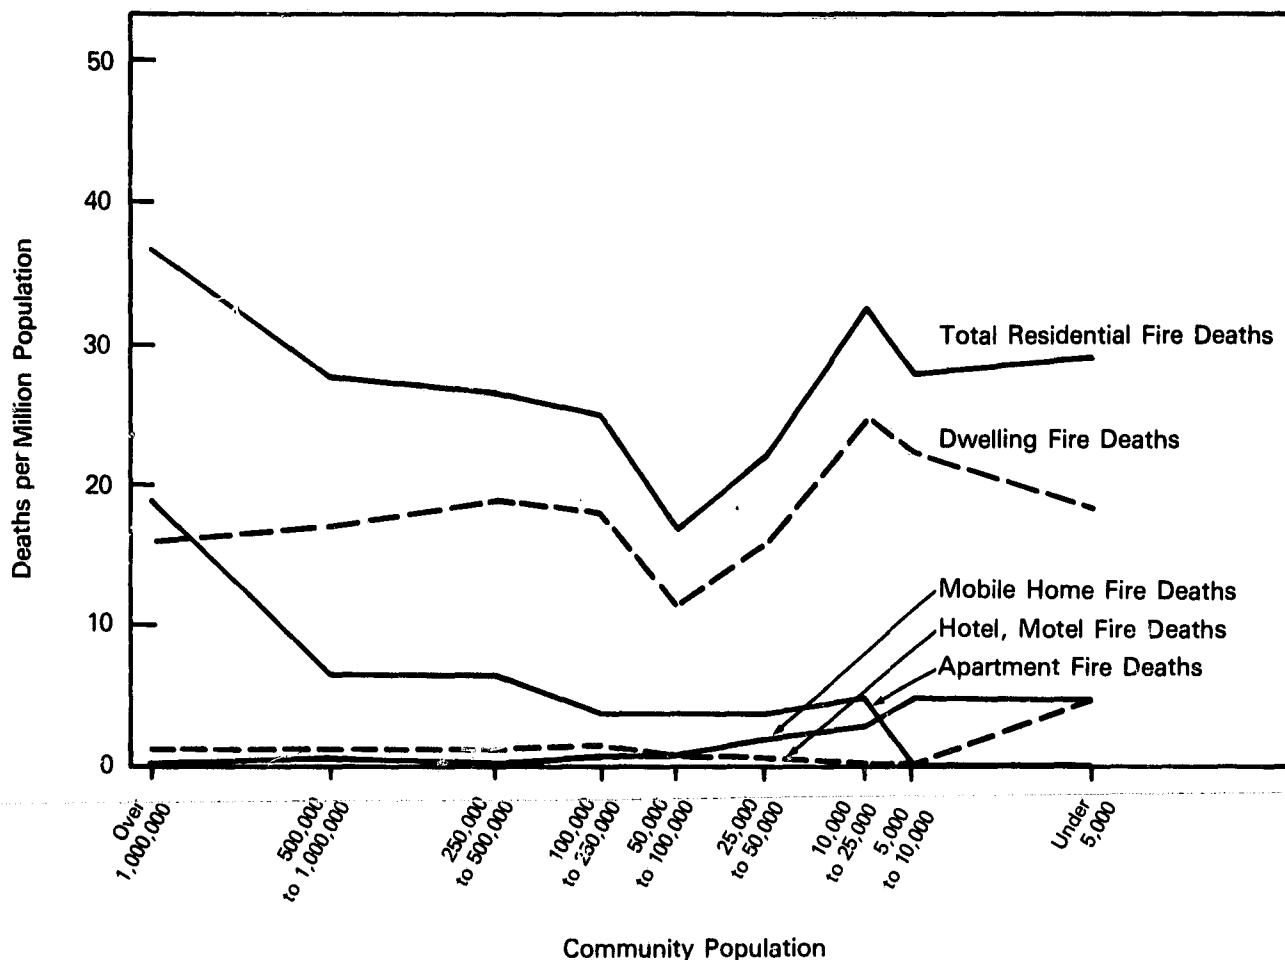

now have early warning protection. Fire deaths probably can be substantially reduced if the units are placed in appropriate locations and receive proper maintenance, and if household members are trained in escaping from their homes.⁴¹

The Ohio data were examined to see whether fires in which detectors were present and operating resulted in fewer deaths, injuries, and losses than when no detectors were present. However, so few cases were reported where de-

⁴⁰ Correspondence with Richard Bukowski, Center for Fire Research, National Bureau of Standards, Gaithersburg, MD.

⁴¹ Halpin, B.M., et al., *The Assessment of Fire Protection Systems Impact on Actual Fire Incidents*, (Laurel, MD: Applied Physics Laboratory, Johns Hopkins University, Fire Problems Program, Technical Report No. 35, August 1977) Fire Administration Grant No. NFPCA-76045. The report indicates that over 90 percent of the fire deaths analyzed in Maryland in 1976 (most of which were residential) probably could have been avoided if smoke detectors had been present.

Figure III-2. RESIDENTIAL FIRE DEATH RATE BY OCCUPANCY TYPE AND COMMUNITY SIZE — 1974 NFPA SURVEY

SOURCE: 1974 NFPA Survey.

tectors were present and operating that the results were not statistically significant. With more detectors coming into use, and more States joining NFIRS, the needed information should be available in the future.

Automatic Sprinkler Performance

The value of automatic sprinklers is illustrated by Table 21. The average loss is significantly less where automatic sprinklers are installed and operating properly than where there are no sprinklers. This is true for all occupancy types examined.

Only 0.2 percent of residential fires and 4.5 percent of non-residential fires attended by the fire service occurred in structures with operating sprinklers.⁴² Given the dramatically lower dollar losses with sprinklers, it is likely that increased use of sprinklers could reduce losses much further. They are especially important in public occupancies, where they are needed above all else for life safety.

⁴² All but 2 of the 39 residential fires with sprinklers occurred in apartment, dormitory, or hotel buildings. We are not sure at this time if the fires occurred in the living quarters or a garage area, although the latter is suspected.

Table 21. EFFECTIVENESS OF AUTOMATIC SPRINKLERS IN STRUCTURAL FIRES—Ohio (NFIRS 1976)

Property Type	Total Number of Fires ¹	(A) With Sprinklers Operating		(B) Without Sprinklers		Damage Ratio ²
		Number of Fires	Average Damage per Fire	Number of Fires	Average Damage per Fire	
Residential	16,970	39	\$ 585	15,022	\$ 3,736	6.4
Public Assembly	783	12	8,958	649	9,820	1.1
Education	271	5	70	230	9,572	136.7
Institutions	474	20	209	307	2,824	13.5
Stores, Offices	1,056	31	9,517	857	16,531	1.7
Basic Industry	96	6	3,767	74	10,739	2.9
Manufacturing	909	182	8,994	523	22,559	2.5
Storage (excluding Residential Garage)	1,238	27	13,859	1,107	17,088	1.2

¹ Reported fire incidents shown here do not include all fires attended by fire departments. Estimated completeness is roughly 50 percent for Ohio (Reference 11). Fires in which sprinklers were present but failed to operate or for which information was not available are not included in columns (A) or (B). 1,083 structure fires falling in the category "Other Property Type" have not been included because there were only two fires reported in which sprinklers were operating. 1,533 residential garage fires are not included because none involved sprinklers.

² Damage ratio = $\frac{\text{Average damage per fire without sprinklers}}{\text{Average damage per fire with sprinklers operating}} = \frac{\text{Column B}}{\text{Column A}}$

PART II

Characteristics of Fires for Selected States and Cities

Section V

Introduction to Part II

This part of the report summarizes detailed fire information from the States of Ohio and California and data from seven cities that use the Uniform Fire Incident Reporting System (UFIRS). Ohio was the first participant in the National Fire Incident Reporting System (NFIRS) and the NFIRS State for which we had the largest amount of standardized data. The California data was collected under the California Fire Incident Reporting System (CFIRS), which is largely compatible with NFIRS.

Although California and Ohio have a combined population of 32 million persons and represent a substantial proportion (15 percent) of the U.S. population, they may not be representative of the country as a whole. In future years, data from many more States will be available so that a detailed nationwide picture may be formed.

Nonetheless, the current data from these States give many insights into the fire problem, and afford some benchmarks for State and local jurisdictions to compare themselves against. The form of the analysis here also may serve as a starting point for State and local jurisdiction to use in their own analyses.

DATA LIMITATIONS

The data presented have significant limitations in both quality and completeness simply due to the newness of NFIRS; the first year of operation was 1976.

In Ohio, especially in the early months of 1976 before data training programs had gotten underway, there were difficulties in interpreting the NFPA 901 codes upon which the detailed reports are based. In instances where misinterpretations may have occurred, these are pointed out in the discussion of the numerical results.

Significant limitations were introduced by not knowing the true percentage of all incidents for which NFIRS reports are submitted. One estimate is that about 50 percent of all fires attended by the fire departments were included in the 1976 Ohio NFIRS data file.⁴³ California's system is older and believed to have more complete reporting. Although the precise degree of completeness is unknown, it is estimated that about 90 percent of the fires are reported. Were the fraction of fires reported more accurately known, estimates of higher confidence could be formulated.

As a result of these limitations, the estimates here of *absolute* magnitudes of fire rates, and comparison between rates in Ohio and California based upon them, may be invalid and misleading. More complete reporting would make these rates higher in the absolute, with Ohio rates increasing more than California. Thus, when rates in this report from Ohio are higher than California's rates, that relationship is likely to be correct. When the California rate is higher, that may be correct or may be due to more complete reporting than in Ohio.

Because large samples are available from both States, we can be confident that the *relative* magnitude of different types of fires is representative of a large part of that problem in each State. We cannot be sure how representative the data are of the whole State, however, although the figures are probably not far off. This is especially true for the death, injury, and dollar loss data which tend to reflect the more significant fires and which are more likely to be reported by the local fire service to the State.

⁴³ Eisenberg, Daniel and Getis, Robert, Principal Investigators, *Initial NFIRS Data Validation Study* (Philadelphia, PA: Auerbach Associates, Inc., March 1977), Fire Administration Contract No. 6-34583.

Finally, it is noted that the California data are for calendar year 1975, while the Ohio data are for 1976. In summary, the data here probably can be used to identify major problem areas, but must be used with caution.

ORGANIZATION OF PART II

In the rest of Part II, data are presented in a succession of tables containing progressively more detail. An initial summary is given in Section VI. Section VII discusses characteristics of the casualties of fires. *Cause categories* pertaining to residential fires are presented in Section VIII.

Detailed information on the *specific ignition characteristics* involved in residential fires is presented in Section IX. From the large amount of reported data, principal emphasis was given to those characteristics believed to be most relevant to local governments in targeting public education, inspections, and code enforcement.

Section X contains a comparison of fire losses for *different cities*. Included in the comparison are Ohio cities and seven other cities using UFIRS, a system that is largely compatible with NFIRS. These NFIRS cities were ones whose data had reasonable completeness and apparent validity and whose data were received in time for this analysis. Finally, the details of *non-residential* fires and their causes are presented in Section XI.

HIGHLIGHTING

The practice here is to discuss only a few significant items from each table. Since Part I summarizes the results of several tables presented below, the emphasis here is primarily on details

of the fire problem not discussed earlier and on differences in patterns.

We occasionally show percentage comparisons for the two States by simply writing, for example, 62 percent (73 percent). Where this is done, the first number, 62 percent, always refers to California; while the number in parentheses, (73 percent), refers to Ohio.

PRECISION

The precision of the numbers appearing in the tables will be low when the number of recorded incidents (fires, deaths, or injuries) is small. The number may be small either as a result of a detailed breakdown into specialized categories of fire, or because the community is small. There is a simple square root formula, discussed in Appendix VI, that relates the precision to the number of reported incidents. Useful benchmarks are: 100 occurrences yields a precision of 10 percent, 25 occurrences 20 percent, 16 occurrences 25 percent, 9 occurrences 33 $\frac{1}{3}$ percent, 4 occurrences 50 percent.⁴⁴

TYPES OF NUMBERS IN THE TABLES

In addition to presenting tables with the *number* of occurrences of fires and casualties, we also have presented tables of *rates*, which are needed for comparing communities, and tables of *percentages*, which show the importance of specific items in relation to the total.

⁴⁴ A precision of 10 percent means that the estimate is "good" to plus or minus 10 percent of its value.

Section VI

Fire Frequency and Loss in Major Occupancy Types

This section summarizes losses and frequency of fires by general occupancy types. The intent is not to make comparisons of the rates between the two example States, but rather to determine similarities in patterns of fires. The main value of the data presented is in relative percentages, not in relative rates.

MAJOR OCCUPANCY CLASSES

Table 22 summarizes fire losses for California and Ohio for the four major occupancy classes—residential, non-residential structure (e.g. public assembly, commercial, manufacturing, storage), mobile property (e.g. motor vehicles, air, rail, water transportation), and outside property (e.g. trash, brush, forests). Since fires in residential properties are discussed in great detail in Sections VIII and IX, little discussion of those fires is given here.

The table presents total incidents, rates, and percents. As noted previously, comparison of rates, especially fire rates, may be misleading because Ohio's reporting of fire incidents is less complete for the first year of NFIRS than California's. The reverse may be true for deaths, because California apparently reports primarily those deaths that occur at the scene of the fire. A useful benchmark for comparison is that, since California's 1975 population (21,185,000) is about twice that of Ohio's (10,759,000) if both States had identical fire characteristics, the numbers reported for Ohio would be about one-half those of California.

One of the significant highlights of Table 22 is that the majority of fires in both States occur on outside property, but these result in the fewest deaths. In Ohio the outside fires also result in the fewest injuries and dollar loss.

Another highlight is that the relative proportions of fire losses among the occupancy types are not too different for the two States. Residential fires account for 75 percent of all fire deaths in Ohio, 64 percent in California. In Ohio non-residential structure fires account for a slightly higher percent of dollar loss than do residential fires. In California the residential dollar loss is slightly higher than non-residential. And the California outside fire loss is a slightly larger part of the losses than it is in Ohio.

LARGE STRUCTURAL FIRES

In Table 23, which is confined to structures, a "large fire" is defined as one that extends beyond the room of origin. From the table it can be seen that about two-thirds of the large fires in each State occur in residential occupancies. Most of the deaths and injuries at large fires occur in large residential fires. But roughly half of the dollar loss from large fires are in non-residential occupancies.

Fire rates for large fires are about the same for the two States. This is very different from what was observed for overall fire rates in the previous table and suggests that reporting of significant fires in Ohio may be much more complete than for small fires, or at least comparable to California.

Death and injury rates for large fires in Ohio are more than double those in California.

NON-RESIDENTIAL STRUCTURE FIRES

Table 24 breaks down the non-residential structure fires into the eight principal NFPA 901 categories (except that "vacant" and "under construction" structures have been separated out from the NFPA 901 "special property" category).

Highlights from the table include: Stores and offices are the non-residential occupancy type having the most fires in each State. The category with the most fires in the table is actually storage occupancies (including garages, warehouses, lumberyards, etc.), but this is somewhat deceptive because the main category of storage fires are residential detached garages. For California, manufacturing occupancies were the leading category for non-residential fire deaths and injuries. For Ohio, deaths and injuries in stores and offices, storage, and manufacturing are all high.

LARGE NON-RESIDENTIAL STRUCTURE FIRES

Table 25 shows the fire losses for "large" fires in non-residential structures—those extending beyond the room or compartment of origin.

One-half (California) to two-thirds (Ohio) of non-residential injuries occur in large fires. Over three-quarters of non-residential dollar losses occur in large fires. This situation is different from residential fires, where the bulk of the problem is a large number of small losses. This suggests that non-residential prevention might initially focus on understanding the cause of the relatively small number of fires that lead to the bulk of the problem, and then focus on preventing those types of fires.

In Ohio, 37 percent of non-residential structure fires are "large"; in California, 21 percent. Although the table indicates that a greater proportion of storage fires result in "large fires" than for any other occupancy—38 percent in California,

54 percent in Ohio—this may be due to describing the fire as "confined to building of origin" when the "room" is the only compartment in the building, as is common for residential garages.

MOBILE PROPERTY AND OUTSIDE FIRES

Table 26 summarizes fire losses for the principal subcategories within mobile property and outside fires. Mobile homes are *not* included in the mobile property category, but rather in the residential category. Some highlights are:

- Automobile fires account for 10 percent of all fires attended by the fire service in California, 16 percent in Ohio. This frequency and the related number of fires may be surprisingly large to the public, which probably is not aware of the seriousness of the problem.
- Deaths from motor vehicle fires represent about 16 percent of all fire deaths in both California and Ohio. This value is somewhat higher than the national average estimate (11 percent) from State Fire Marshal data given in Appendix IV.
- In California, losses from outside fires are considerable: 662 injuries, \$16.6 million property loss.
- The number of forest and crop fires and their losses are small, but this may be due to failure to report these fires to fire departments. (This "small" appearance clearly is *not* the case in California for 1977.)

¹ Large fires are defined as those fires which extend beyond the room of origin.

² Reported fire incidents shown do not include all fires attended by fire departments. Estimated completeness is on the order of 90 percent for California and 50 percent for Ohio (Reference 11).

³ Percentages of large fire losses by property type were calculated as follows:

$$\text{Percent by property type} = \frac{\text{Number due to large loss fires by property type}}{\text{Number due to all fires by property type}} \times 100$$

The number due to all fires by property type may be found in Table 24.

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than two were rounded to the nearest tenth of a percent.

Section VII

Characteristics of Fire Casualties

The most important aspect of fire protection is life safety. In addition to knowing where and why fires occur, it is necessary to know what groups of people are most likely to be victims and what the circumstances and nature of the casualties are. It is also important to differentiate between firefighter casualties and general public casualties because their nature and the remedial actions called for are likely to be quite different.

This section presents characteristics of civilian and firefighter casualties. Civilian casualties are discussed by age, sex, nature and causes of casualty, and body parts injured. The results are based primarily on NFIRS casualty data for Ohio, since California did not report corresponding details. However, selected comparisons of fire casualties are also presented for the seven UFIRS cities.

In examining the data in this section, it should be noted that casualty data has some special validity problems. Minor injuries may or may not be reported. Major nonfatal injuries cannot be distinguished in the current NFIRS from minor injuries, since the NFIRS reporting form does not contain a data element relating to the severity of a nonfatal injury. Reporting of firefighter injuries may be influenced by local pension and insurance reporting requirements, which differ from place to place. Reporting a minor injury is sometimes discouraged by peer pressures and by the paperwork involved. Because of the problems and the importance of the issue, improving injury reporting is a high priority on the National Fire Data Center's agenda.

OHIO FIRE CASUALTIES BY AGE AND SEX

The distribution of civilian injuries by age and sex, and firefighters injuries by age are shown

in Table 27. Highlights of that table are:

- Over half (56 percent) of all injuries from fires attended by the fire service in Ohio are to firefighters. There were five firefighter deaths reported in 1976.
- Sixty-five percent of all civilian injuries and 61 percent of fire deaths in Ohio are to males. This agrees with the National Center for Health Statistics death data presented in Figure 2, page
- The reason for the surprisingly high percentage of male casualties is not known; this subject will receive further study.
- Not only do male victims outnumber female victims overall, but also civilian male fire injuries in Ohio are more frequent than female injuries for all age groups under 65 years. The situation reverses at the over-65 category, possibly because there are many more females surviving to that age than men. Deaths follow the same pattern except for the 6-17 age group.
- Almost two-thirds of firefighter injuries in Ohio are to individuals between the ages of 26 and 45: 39 percent between 26 and 35 years; and 25 percent between 36 and 45 years.
- The age distribution of civilian injuries is quite different from that for civilian deaths. About three-quarters of all civilian injuries occur to persons between 18 and 65 years of age, but only half of the deaths. Persons less than 18 years have only 18 percent of the injuries, but 30 percent of deaths. Persons more than 65 years have only 9 percent of the injuries, but 21 percent of deaths. Clearly, the nature of fire encountered and the response of the victim to the fire situation and to treatment varies significantly with age.

From another point of view, one can consider the relative risk for each age group. Relative risk is the percent of injuries or fatalities in

each age group divided by the percent of the people in that age group. A relative risk of "one" is by definition normal or average; higher than "one" means higher risk.

As can be seen from Table 28, the greatest risk of death by fire is to those over 75 years, followed by those under 6 years. The results for Ohio are basically in agreement with the death rates for different age groups reported by the National Safety Council (Figure 9, page 25) for the Nation.

² Includes heart attacks and strokes.

tion concerning the degree of reporting of injuries, especially minor ones.

For civilians, the data show:

- The most frequent fire injury to civilians is burns alone, with smoke inhalation second. Burn and smoke injuries which occurred separately or together account for 83 percent of injuries.
- Males have many more burn injuries than females and many more wounds than females. There is no category here in which females have significantly more injuries than males.
- The largest category of civilian deaths in Ohio is burns and smoke inhalation at the same time (55 percent). Burns and smoke inhalation, separately or together, account for 78 percent of deaths. (It is not apparent from this data whether

smoke inhalation was the prime cause; but other, more detailed studies point that way.⁴⁵)

For firefighters, the data show:

- Smoke inhalation is the most common injury in Ohio (25 percent), followed by strains or sprains (17 percent), and cuts or wounds (17 percent). Only 11 percent of firefighter injuries are burns alone.
- Of injuries sustained in connection with a fire in Ohio, 83 percent are incurred during fire control activities.⁴⁶ Another 3 percent are incurred in transit to or from the fire, 4 percent during rescue attempts, 6 percent during overhaul, and 4 percent during other activities.

⁴⁵ Halpin, Byron M. et al, "Fire-Related Fatalities: An Analysis of Their Demography, Physical Origins, and Medical Causes," *Fire Standards and Safety*, American Society of Testing Materials, STP 614, (1977), pp. 26-54.

⁴⁶ This finding is based on additional analysis of the Ohio data.

• Firefighter deaths in Ohio were too few to make any generalizations. However, a recent joint IAFF/NBS/NFPCA study shows that almost 45 percent of on-duty firefighter deaths are due to heart attacks or other cardiovascular accidents.⁴⁷

OHIO FIRE CASUALTIES BY CAUSE OF CASUALTY

Table 30 summarizes the causes of casualties. "Cause" is used here in the sense of the immediate physical condition or action that led to the injury.

⁴⁷ Balanoff, Thomas, *Fire Fighter Mortality Report* (Washington, DC: International Association of Fire Fighters for the National Fire Prevention and Control Administration and the Center for Fire Research, Institute for Applied Technology, National Bureau of Standards, May 1976), Contract Number 4-35909.

"Exposure to fire products (including flame, heat, smoke, and gas), chemicals, or radiation" resulted in 75 percent of civilian injuries and 70 percent of civilian deaths. This category is most applicable to burn or smoke inhalation casualties in the previous section, which accounted for 83 percent of injuries and 79 percent of deaths.

Only 44 percent of firefighter injuries are from "exposure to fire products." That is, most firefighter injuries in Ohio (specifically, the remaining 56 percent) are not directly from the fire, but rather from working near the fire and falling or being struck by something or from over-exertion. This suggests that in addition to improving turnout gear and breathing apparatus, there is a need for more training in fire safety.

¹ Tabulations based on numbers reported on the Ohio 1976 NFIRS Casualty Forms.

² Includes flame, heat, smoke, and gas.

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error.

At least 19 percent of firefighter injuries are caused by falling or stepping on, over, or into something. Another 11 percent of firefighter injuries are due to contact with some object. Approximately 6 percent of firefighter injuries are due to over-exertion. Civilians are much lower in each of these categories, which provides another rough face-validity check. It is not surprising that firefighters get injured by working around the fire; whereas, most civilians flee from the fire if able to do so; and if not injured by smoke or flame, they are unlikely to suffer strains, sprains, or be hit by objects.

OHIO FIRE CASUALTIES BY PART OF BODY INJURED

Table 31 indicates the frequency of injuries to various parts of the body. For both firefighters and

civilians, about one-third of all injuries are "internal," mostly from smoke inhalation. The majority of firefighter injuries in Ohio are about equally divided among various parts of the body: 11 percent each for (1) head and neck; (2) hand; (3) body, trunk, and back; and (4) leg. Arm injuries are 9 percent. A recent IAFF study also found firefighter injuries well distributed over the body.⁴⁸ These results suggest that improvement is needed for all parts of the firefighter's protective outfit—no single weak point is evident. Severe but nonfatal injuries might be more concentrated, however, and should be analyzed before any final conclusions are drawn.

⁴⁸ *A Comprehensive Study of Firefighter Injuries and Injury Reporting Systems* (Washington, DC: International Association of Fire Fighters, October 1977), Fire Administration Grant Number NFPCA-76056, p. 82. The study results are based on a survey conducted in 13 cities.

¹ The Denver Fire Department has jurisdiction over Denver City and County.

² Civilian injuries/million population, civilian fatalities/million population, firefighter injuries/1,000 firefighters, firefighter fatalities/1,000 firefighters.

³ The "burns and asphyxia/smoke" category was not designated on the UFIRS Casualty Forms for these cities.

⁴ Comparable categories not available.

⁵ Category designated was "wound or distorted member."

⁶ Includes 763 full paid, 15 part paid, and 296 volunteer firemen.

** Means cannot compute, denominator unavailable.

— Means data not available.

SOURCE: Based on data from the Ohio NFIRS (using the NFPA 901 codes for 1976), and from the UFIRS system of each city (which use the NFPA 901 codes for 1973 and 1971).

FIRE CASUALTIES IN SEVEN UFIRS CITIES

Table 32 summarizes selected casualty data from the seven UFIRS cities previously noted. For comparison, data from Ohio is included in the table.

From the table it can be seen that reported fire-fighter injury rates vary nearly ten-fold—from 33 per thousand firefighters to 300 per thousand. These enormous differences may be due to different reporting practices or different city characteristics, different firefighting practices, or training. They imply the need for follow-up analysis to improve the comparability of the statistics and

to identify any transferable successes in reducing injury rates.

From the table it can also be seen that fire-fighter injuries range from 16 percent of total reported injuries for Denver to 77 percent for Kansas City. Some of the discrepancies might be due to differences in reporting practices or to the fact that urban firefighters may be exposed to hazardous fires more frequently than rural firefighters—rural fires are included in the Ohio data.

Reported civilian injury rates (injuries per capita) vary five-fold, from an extraordinarily low rate of 98 per million persons, to 530 per million. The number of deaths in the table is too small to provide reliable comparisons.

Section VIII

Residential Fires

This section contains tables showing the relative frequency of the causes of residential fires. In this section we use the same cause categorizations discussed earlier in Section IV, page 33. Appendix IX provides tables showing the same breakdowns, but presents the number of fires and their rates instead of relative frequencies.

SUMMARY OF CAUSES OF RESIDENTIAL FIRES

Table 33 shows the relative frequency of fire losses attributed to different causes of reported residential fires. There are eight major cause categories: cooking, smoking, heating, incendiary or suspicious, electrical distribution, appliances, children playing, and open flame or spark. For fires of *known* cause, these together account for 90 percent (89 percent) of all residential fires, 93 percent (91 percent) of deaths, 92 percent (87 percent) of injuries, and 89 percent (87 percent) of losses.⁴⁹

The top four major known cause categories for both States are cooking, smoking, heating, and incendiary or suspicious. For fires of known cause, these four categories account for well over half the fire problem any way you look at it: 63 percent (60 percent) of all residential fires, 80 percent (66 percent) of deaths, 68 percent (59 percent) of injuries, and 62 percent (55 percent) of dollar losses.⁵⁰ These numbers suggest that both States should consider focusing fire prevention programs on these four areas to achieve significant reductions in fire losses. Of course, programs also are needed in other areas to prevent new problems arising.

⁴⁹ Unless specifically noted, the remaining discussions of this section will be in terms of percentages of all fires (i.e. those of known and unknown causes). The first figure refers to California; the figure in parentheses is for Ohio.

- *Cooking* is the most frequent cause of all reported residential fires in both States: 19 percent (16 percent). This is no surprise. It is also the second highest cause of death in both: 7 percent (10 percent). This is less obvious; cooking is not often thought of as causing other than trivial fires.

- *Smoking* ranks first by far as the cause of fire deaths in both States: 37 percent (18 percent). It is also first or second as the cause of injuries: 14 percent (12 percent). Further, it is the second most frequent cause of fire⁵⁰ in both States: 13 percent (14 percent).

- *Heating fires* are the third most frequent cause of residential fires in both States.

- *Incendiary or suspicious* residential fires are the fourth most frequent cause of residential fires but are the most frequent in both States in dollar loss: 17 percent (14 percent).

- Fires caused by *children playing* rank eighth in California (4 percent), but fifth in Ohio (8 percent).

- Fires caused by *open flame or spark* are a larger part of the problem in California (6 percent) than in Ohio (3 percent). Recall that "open flame or spark" does not include fires that have been assigned to any of the seven preceding cause categories—see priority list, page 36. For example, "children playing with matches" are not included in "open flame or spark."

- *Exposure* causes about 3 percent of reported residential fires. "Exposure" in building fires means "ignited by heat from another hostile fire." The most common mode is from the burning of outside trash. Less frequently, it includes ignition from another building.

⁵⁰ Possibly many fires attributed to smoking should more properly be classified as unknown cause.

Total Percent Residential	99%	99%	100%	99%	100%	100%	100%	101%
Total Number Residential¹	46,585	16,970	270	201	2,745	2,348	\$94,274²	\$61,335²

¹ Reported fire incidents shown do not include all fires attended by fire departments. Estimated completeness is on the order of 90 percent for California and 50 percent for Ohio (Reference 11).

² Dollar loss in thousands.

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than two were rounded to the nearest tenth of a percent.

• Fires of *unknown* cause comprise 11 percent of all fires in California and 8 percent in Ohio. It is the leading dollar loss category in both States: 17 percent (14 percent). In Ohio unknown cause is also the leading category for deaths (35 percent), occurring almost twice as often as smoking which is the most frequent of the known causes; in California unknown causes (27 percent) are second to smoking (37 percent). In Ohio unknown cause also leads the list of causes for injuries (15 percent).⁵¹

⁵¹ A change in any year in the relative frequency of fires of unknown cause may create some difficulty when monitoring trends for individual cause categories. For example, an apparent decrease in incendiary/suspicious fires or smoking fires may actually be the result of reporting more fires of doubtful cause as fires of unknown cause. This problem can be reduced by considering causes as a percent of fires with known causes, rather than as a percent of all fires.

FREQUENCY AND CAUSES BY TYPE OF RESIDENCE

Table 34 shows how causes are distributed among different types of residences. Fires occur most frequently in one and two family dwellings—three times as often as fires in apartments in both States. They account for 68 percent (75 percent) for all residential fires, 62 percent (72 percent) of deaths, 64 percent (74 percent) of injuries, and 71 percent (79 percent) of dollar loss. However, one- and two-family dwellings do not necessarily represent a higher fire risk than apartments or mobile homes. This type of analysis would require knowing the relative number of buildings or households of each type.

Hotels and motels as well as other miscellaneous residences such as dormitories, are sites of a very minor part of residential fires today. But

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than two were rounded to the nearest tenth of a percent.

again, one would need to know the number of persons occupying these types of residences before saying that the rate of danger is especially high or low.

The cause profile for apartments is somewhat different than for single-family dwellings in both States. This difference suggests a need for different emphasis in prevention programs. For example, smoking-related fires account for twice

the percentage of apartment fires, 22 percent (22 percent), as one- and two-family dwelling fires, 8 percent (11 percent). Fires involving heating equipment are half the percentage of apartment fires, 7 percent (5 percent), as in one- and two-family dwellings, 16 percent (15 percent).

Although not shown in Table 34, fires involving people smoking are the principal cause of death for each residential occupancy.

Section IX

Detailed Characteristics of Residential Fires

This section presents more detailed information on the characteristics of the major causes of residential fires that were previously identified for California and Ohio. From the various data elements included in the NFIRS reporting form, we have selected those cause categories most likely to be useful in targeting local fire prevention programs. For the cause categories primarily involving equipment, the most important additional information needed is the ignition factor. For causes not involving equipment, information on the form of heat of ignition, type of material ignited, form of material ignited, and area of origin may also be pertinent.

For each of the equipment cause categories, detailed breakdowns are given by the principal NFPA 901 code subcategories of equipment. As noted previously, this breakdown makes it possible to redefine cause categories, if desired. For example, one could separate fireplace fires from the general heating category or include portable heaters or hot plates in the appliance category.

For each equipment category, the causes of ignition are subdivided into malfunction, design-construction-installation deficiency, and misuse or carelessness. The NFPA 901 codes further subdivide misuse according to misuse of heat, misuse of material ignited, and operational deficiency.

The order in which the leading causes are discussed below is their relative frequency for both States combined; the most frequent cause, cooking, is discussed first.

RESIDENTIAL COOKING FIRES

According to the 1974 National Fire Household Survey, the vast majority of fires in the home arise from cooking. (See Section IV, page 44 for a summary.) Most of these fires are not reported to the fire service—they are small and are extin-

guished by the resident or go out by themselves. The reported cooking fires tend to be more serious.

According to the data in Table 35, in both Ohio and California human errors account for about three-fourths of residential fires involving cooking. In both States this same factor accounts for a similar fraction of the injuries, deaths, and dollar losses. Mechanical failure or malfunction usually account for much less than one-fourth as many fires, injuries, deaths, or dollar losses as carelessness.

The single most common specific cause of fires involving cooking is leaving cooking "unattended"—43 percent of the cooking fires in Ohio and 27 percent in California. This ignition factor also accounts for the highest percent of cooking-related injuries, deaths, and dollar losses. It includes a person being physically absent from the kitchen, but may also apply to any situation, not otherwise more specifically classified, when the person is conscious, but inattentive to the cooking. This behavioral problem far outnumbers mechanical problems, such as shorts and part failures. Comparatively few cooking fires are reported as caused by somebody starting to cook then falling asleep, though some of these might have been reported as "unattended."

"Accidentally turned on or not turned off" equipment is the second most common type of misuse: 9 percent (5 percent) of all cooking fires. In California, "combustible-too-close" ranks a close third.

Although not shown in Table 35, almost 90 percent of residential cooking fires have stoves and ovens as the type of equipment involved. This probably is due to their vast predominance over other types of cooking equipment.⁵² The

⁵² See Appendix X for the frequency distribution of cooking fires.

characteristics of these fires are further analyzed below.

Residential Cooking Fires Involving Stoves and Ovens

The nature and frequency of specific causes of residential fires involving stoves or ovens for cooking, shown in Table 36, appear to depend in part upon whether the appliance is gas or electric. The source of heat is unknown for many reported cooking fires, because there are several ways to code certain causes, some of which do not indicate whether a gas or electric source of heat is involved. The relative risks cannot actually be assessed without a more accurate determination of electric or gas and without knowing relative numbers of each in homes.⁵³ However, if we look just at the incidents where gas versus electric is coded, patterns of incidents emerge which can be used in identifying the specifics of the cooking problem and in planning prevention programs.

Some highlights of Table 36 include:

- Stoves are much more often the source of fires than ovens in the two States, possibly because of more frequent use and the presence of an open heating element.
- In Ohio, fires from electric stoves outnumber fires involving gas stoves by almost 35 percent. In California, however, they are tied.
- In California, gas oven fires outnumber electric oven fires by two to one. In Ohio, gas oven fires also are more frequent, but not by as much as in California. Note again that these are not relative rates of failure for each type of appliance relative to its numbers, but rather the *proportion* of cooking fires that involved them.
- Fires caused by "accidentally turned on or not turned off" stoves are more frequent for electric than for gas stoves.
- A larger percentage of fires for gas stoves involve "part failures" than for electric stoves—but this may be a reporting artifact, since part failures leading to shorts might not be included for electric stoves.

Material Ignited in Cooking Fires

Table 37 shows that the material most frequently ignited in stoves and ovens is, as ex-

⁵³ Analysts can use sales or consumer product consensus data to convert the raw cause data to rates.

pected, grease: 48 percent (57 percent). The next most important is food: 18 percent (14 percent). Together these are the first ignited materials in over two-thirds of stove and oven fires. Plastic on electric stoves and ovens also is ignited fairly often. On the other hand, fabric is ignited much more often for gas.

RESIDENTIAL SMOKING-RELATED FIRES

Fires involving people smoking are the second most frequently occurring type of residential fire. Table 38 presents statistics on the origin of fires related to smoking.

In Ohio, 94 percent of fires related to smoking are caused by cigarettes, but in California only 69 percent. The difference may be more apparent than real, however, and may be the result of different coding practices when one is not certain that a cigarette was involved. In California, the unknown smoking materials category represents a relatively high proportion, 27 percent, compared with only 3 percent in Ohio. With the unknowns deleted, the profiles in the two States would be very similar.

"Falling asleep" was reported as a factor in a surprisingly small percentage of smoking-related fires—11 percent in California and 14 percent in Ohio. But it accounts for a large proportion of smoking-related deaths, especially in California, 44 percent (17 percent), and injuries, 28 percent (23 percent). The condition "unconscious" was not reported in any of the fires.

In both States over 40 percent of smoking-related fires occur in the bedroom and 26 percent in the living room; one-third occur elsewhere. Of the smoking-related fires causing *deaths*, 51 percent start in the bedroom in California; whereas in Ohio, 63 percent of fires causing deaths start in the living room.

Materials First Ignited in Smoking Fires

Knowledge about the material first ignited is important, especially for setting State or Federal flammability standards or conducting research into flammability of materials exposed to burning cigarettes, and in alerting industry to the potential need for improved products. Both the form (or usage) of the material as well as the type (or composition) are relevant. The breakdown in Table 39 is according to the NFPA 901 codes.

¹ Reported fire incidents shown do not include all fires attended by fire departments. Estimated completeness is on the order of 90 percent for California and 50 percent for Ohio (Reference 11).

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than one were rounded to the nearest tenth of a percent.

Upholstered chairs and sofas, mattresses, and bedding are the items most frequently involved in residential fires caused by smoking, 57 percent (69 percent). It should be noted that the distinction between bedding materials and mattresses may not always be correctly coded. There are significant differences reported between California and Ohio. Although bedding materials account for the same percentage of residential smoking fires in both States, they account for twice the percentage of deaths in California than in Ohio, 29 percent vs. 14 percent. On the other hand, residential smoking fires involving upholstered chairs or sofas account for about half the percentage of deaths in California than in Ohio, 36 percent vs. 60 percent, although again the

category accounts for about the same percentage of fires, 31 percent and 28 percent. In other words, smoking fires occur in the same places in both States, but they happen to result in more lethal fires in beds in one and in upholstered furniture in the other. Whether this is happenstance or has an underlying reason remains to be seen. The number of deaths is small, so that the precision is low.

Ignition of fabric (including natural or man-made fabrics or fur) resulted in 61 percent (64 percent) of smoking fires, 77 percent (69 percent) of deaths, 73 percent (75 percent) of injuries, and 65 percent (67 percent) of dollar loss. The type of material most often involved was reported as cotton or rayon; but in upholstery, synthetics

occurred with moderate frequency; in Ohio they occurred more frequently than cotton or rayon.

RESIDENTIAL HEATING-RELATED FIRES

Fires involving heating equipment are the third most frequently occurring residential fires in both States, despite differences between their climates. In fact, California has many more such fires per capita than Ohio (more even than are likely to be accounted for by under-reporting).

Table 40 provides a breakdown of causes of residential heating fires by type of heating equipment. Overall, central heating is the most frequently involved type of heating in Ohio (29 percent). Fixed local heating equipment is most frequent in California (27 percent), probably reflecting differences in climate and construction practices. In both States, fireplaces rank a close second—24 percent of heating fires in Ohio and 23 percent in California. Water heaters rank third.

In California, heating fires are caused about as often by misuse of equipment (40 percent) as by equipment failures or design-construction-installation deficiencies (37 percent); the miscellaneous category ("other") is also large (22 percent). In Ohio, equipment and design/construction problems dominate (56 percent), although misuse still accounts for 37 percent.

Of residential fires involving central heating, "combustibles stored too close" and various mechanical failures account for most incidents in California. In Ohio, a variety of mechanical and other problems account for the majority of the central heating equipment fires.

Among fires in central heating equipment, the most frequent involve mechanical malfunctions: 52 percent (58 percent). The most frequent fires with a design-construction-installation deficiency cause occur in chimney-flue-and-connectors (for California) and fireplaces (for Ohio).

For fires in fixed local heating, the major problem in California is "combustibles stored too close." Part failure is also a frequent problem. In Ohio, no single cause dominates for fires in fixed local heating.

For portable heaters and water heaters, again, "combustibles stored too close" is the leading problem in California. In Ohio, "improper con-

tainer" is most frequent; this may represent a data coding problem rather than an actual problem. Short circuits are also common in both States.

For fires in fireplaces, faulty construction, installation, or design are the principal causes in Ohio. No single cause dominates in California fires of this type. Relevant to this problem, the 1976 Montana State Fire Marshal's report said:

"With the cost of heating being what it is, many people are going more and more towards using fireplaces, coal stoves, and wood burning stoves for heating their homes. Many of these people are not aware of the proper maintenance of these types of heating equipment and are, therefore, letting soot build up in the chimneys or using no spark screens. These have been the two largest problems in the reported heating equipment fires. Also improper installation has been a problem. Fire departments throughout the state would do well to make the people in their community aware of these problems, thereby possibly eliminating a tragedy or fire problem."⁵⁴

Type of Fuel Used in Central Heating

The relative frequency of fires in residential central heating by type of heating fuel and cause of the fire is shown in Table 41.

For fires in central heating for which the fuel type was reported, gas was the predominant type involved. However, to determine the relative risks of the different types of central heating, one must know the relative frequency of use of fuel types. Although not included here, it is desirable to make this type of analysis. It is also useful to know how the type of fuel used in central heating affects the causes of fires.

Table 41 also shows that for gas fuel, only 30 percent (42 percent) of heating-related fires are due to malfunctions and another 44 percent (37 percent) are due to misuse of the material ignited. However, the large number of fires where the type of fuel was not recorded might change these proportions.

⁵⁴ Montana State Fire Marshal Bureau—Annual Report 1976 (Helena, MT: Department of Justice, 1976), p. 13.

RESIDENTIAL INCENDIARY OR
SUSPICIOUS FIRES

In the combined data for California and Ohio, fires of incendiary or suspicious origin are the fourth most frequently occurring type of residential fire. Those fires, accounting for 11 percent of all residential fires, require information different from that of other fires; for example, characteristics and motivation of the perpetrators—their age, relation to property burned, and motivation (e.g. fraud, revenge, vandalism). The information routinely provided by NFIRS is necessarily much narrower in scope than this and requires supplemental data from in-depth studies in the future.

Nevertheless, Table 42 reveals some important findings on incendiary and suspicious fires, based on currently available data. Suspicious fires (that is suspected, but not confirmed, as incendiary) comprise over 40 percent of the total reported as "incendiary or suspicious." This, together with the large percent of fires of "unknown" cause, suggest the need for better arson detection methods and training.

Incendiary devices are listed as the source of ignition relatively infrequently, 5 percent (10 percent). These fires do not account for much of the losses. The most common source of ignition is a match or other flame. However, the "unknown" source of ignition is listed for a sub-

Table 42. CHARACTERISTICS OF INCENDIARY/SUSPICIOUS FIRES

¹ Reported fire incidents shown do not include all fires attended by fire departments. Estimated completeness is on the order of 90 percent for California and 50 percent for Ohio (Reference 11).

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than two were rounded to the nearest tenth of a percent.

stantial proportion of these fires, 37 percent in California, 22 percent in Ohio, and some of these may be from incendiary devices.

Gasoline, kerosene, and other flammable liquids are seldom listed as the material first ignited. Only about 16 percent of these fires list flammable liquids as the material first ignited. Paper is used slightly less often. Fabric and wood are high: 37 percent (43 percent). This may be due to misreporting, since wood and fabric may be the second material ignited, not the first. This is something to be checked in the future.

RESIDENTIAL ELECTRICAL DISTRIBUTION FIRES

Residential fires involving electrical distribution equipment constitute 7 percent of the residential total. A variety of electrical components is included in the electrical distribution category: fixed wiring, lamps and lighting fixtures, cords and plugs, switches and outlets, light bulbs, and so forth. Light bulbs are somewhat different from other items in the category and should perhaps be placed in a separate class. If a fire originates from an electrical rather than a light bulb malfunction, it should not be coded as a light bulb fire, although this practice may not always be followed.

Among electrical distribution fires shown in Table 43, fixed wiring is the most frequent source in both States, 25 percent of electrical fires in California, 31 percent in Ohio. "Cords and plugs" rank second in both States.

Regardless of the particular electrical component involved, equipment malfunction is the principal reported cause of electrical fires, 59 percent in California and 77 percent in Ohio. "Short circuit" is the most frequently reported malfunction, 37 percent (56 percent) of all fires. According to the data, overloaded circuits are much less frequently cited, although still important. However, overloads produce heating which might be reported as a short circuit. Many fire officers have raised caution flags about the accuracy of the reporting of the precise cause of electrical fires.

In California "combustibles too close to heat" is a frequent specific cause for lamp and fixture fires (19 percent) and also for light bulb fires

(27 percent). Although in Ohio "improper container" is most frequently reported for light bulbs, much of this difference may be due to differing interpretations of the codes or to encoding error.

RESIDENTIAL FIRES INVOLVING APPLIANCES

Characteristics of fires involving "appliances," which account for 7 percent of the residential fires, are shown in Table 44 by appliance type and cause. "Appliances" here include TV's, dryers, washing machines, irons, electric blankets, and assorted other items. Appliances used in cooking (e.g. ovens, stoves, deep-fat fryers) and heating (e.g. portable space heaters), air conditioners, and refrigerators are covered elsewhere under those separate headings.

The data in the table indicate that dryers are the appliance in this category most frequently involved in residential fire, 32 percent in California, 38 percent in Ohio. Television and radio fires occur second most frequently, 26 percent (29 percent), but are most frequent in dollar loss by far. TV and radio fires also accounted for most of the small number of deaths resulting from "appliance" fires.

Malfunctions are reported as the ignition factor for 60 percent (73 percent) of the appliance fires. The appliance category with the greatest proportion of fires reported due to malfunctions is TV/radio, 85 percent (89 percent). The appliance category having the greatest proportion of misuse reported is "portable appliances producing heat" (such as irons), 34 percent (33 percent).

For all appliance fires except those involving dryers, short circuits are reported as the principal type of malfunction. As noted when discussing electrical distribution fires, this may be a euphemism for a variety of electrical problems. For appliance fires involving dryers, "worn out or lacking maintenance" and "automatic control failure" are cited more frequently than short circuits.

As with previous categories such as heating and electrical distribution, "combustibles too close" (California) and "improper container" (Ohio) are the most common forms of reported misuse of appliances.

¹ Reported fire incidents shown do not include all fires attended by fire departments. Estimated completeness is on the order of 80 percent for California and 50 percent for Ohio (Reference 11).

NOTE: Some column totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than one were rounded to the nearest tenth of a percent.

The accuracy of the reasons for failure of dryers and other appliances is uncertain. For example, it is difficult to be certain if the cause of a given fire in a dryer was due to an overload condition, failure to clean out lint, or a malfunction. This may be difficult to determine with the investigative resources available for most fires.

RESIDENTIAL FIRES RESULTING FROM CHILDREN PLAYING

In the combined data for California and Ohio, residential fires resulting from children playing are the seventh most frequently occurring type of fire. These fires account for 5 percent of all residential fires. The relative frequency of these fires by ignition characteristic is shown in Table 45.

Among the highlights of Table 45 is that matches are the most frequent ignition source in residential fires caused by children playing. Matches were used in 56 percent of fires in this

category in California, 68 percent in Ohio. Cigarette lighters were second, 8 percent (13 percent).

Residential fires caused by children playing occur in just about any room, but most frequently in bedrooms, 35 percent (48 percent). In California garages are also a frequent location.

Mattresses or bedding are the forms of material most frequently ignited by children playing, 23 percent (39 percent). In Ohio, upholstered chairs or sofas are second (11 percent); in California, however, trash is second (8 percent). Clothes that are not being worn at the time is another item frequently ignited by children.

Relatively few fires caused by children playing ignite clothing worn by children, 8 incidents in California, 13 in Ohio. Possible reasons for this surprisingly low number are (1) standards for making ignition-resistant clothes for children, which were initiated about 1970, may be having significant effect; and (2) clothing ignitions are traditionally under-reported to the fire service. In many cases the child is rushed immediately to the hospital without calling the fire department.

Section X

City by City Fire Data

Up to this point, we have discussed statewide and national results. But the fire problem varies in its detail from community to community, and each must consider its own problems and establish its own priorities. Setting the priorities for solving problems in each community is the heart of master planning for fire protection.⁵⁵

Many communities also are interested in knowing how their fire experience compares to others, both in specific areas and overall. It is also important from a national perspective to know how diverse the problem is from place to place, to aid in developing appropriately responsive programs. And it is also important to identify communities that are performing exceptionally well. Why have they been successful? Can their techniques be transferred to other communities?

For all of these purposes, the fire problem requires looking at the data community by community and not just aggregating at the State or national levels. This section describes the statistical differences in fire and loss rates among Ohio cities and among seven of the cities using the NFPA Uniform Fire Incident Reporting System (UFIRS). (As mentioned earlier, this was the data available for this study; a broader base is expected in future years.) The comparisons were made first according to major occupancy type, and then in more detail for residential fires. There is a risk in doing this. The rate comparisons are affected by differences in reporting among the various communities. In addition, the numbers of fires, deaths, and injuries, and the dollar losses in the city tables are, of course, much fewer than in the previous State tables. This means that the preci-

sion at the city level will be much lower than at the State level, as noted in Section V, page 59 and discussed more fully in Appendix VI. This lower precision in turn lessens the confidence in the inferences that can be drawn from the data.

There are important differences between communities which affect fire rates and losses, and which are beyond control of the fire service or even the community. Ideally, comparisons should be made only between cities with similar "uncontrollable" conditions. The question of which factors should be used to group like communities is currently being investigated by NFPCA, NFPA, and others.

SUMMARY OF CITY BY CITY FIRE DATA

Although the first year's data from NFIRS for the Ohio cities is known to be incomplete, we will discuss it here anyway, to illustrate the types of inter-city analyses that can be made. The data on the absolute numbers of fires and their rates per capita (Tables 46, 47, 48) do not accurately indicate the fire performance of the cities involved. However, the numbers of fires shown indicate the size of the samples we worked with. They are non-random samples but are sufficiently large that they do indicate the broad characteristics of the fire picture in these cities with reasonable accuracy. The information on percent of residential fires by cause (Table 48) is likely to be closer to the mark than either the absolute numbers of fires or the fire rates.

Tables 46 and 47 summarize fire incidents and losses by major occupancy category for each of the 20 largest Ohio cities. These are also the Ohio cities designated as "central cities" by the Bureau of Census. All have a population over 50,000. The remaining Ohio communities are shown only as totals for two groups: 25,000-

⁵⁵ *Urban Guide for Fire Prevention and Control Master Planning*, prepared by the Mountain View and Los Angeles City Fire Departments and the Mission Research Corporation (Washington, DC: Government Printing Office 1977), Fire Administration Grant No. NFPCA-75006.

¹ Reported fire incidents shown do not include all fires attended by fire departments. Estimated completeness is on the order of 90 percent for California and 50 percent for Ohio (Reference 11). For the cities shown the degree of completeness varies from one population group to another, with the larger cities tending to have greater completeness. Care should be taken, therefore, in comparing these cities.

² The Denver Fire Department has jurisdiction over Denver city and county.

³ The total dollar loss for the UFIRS cities excludes Syracuse, which does not record that information.

SOURCE: (1) 1975 CFIRS, (2) 1976 NFIRS, (3) 1976 UFIRS, except Kansas City which was May 1975-April 1976.

¹ Fires/100,000 persons, deaths/million persons, injuries/million persons, dollar per capita. The reported fire incidents on which these rates are based do not include all fires attended by fire departments. Estimated completeness is on the order of 90 percent for California and 50 percent for Ohio (Reference 11). For the cities shown the degree of completeness varies from one population group to another, with the larger cities tending to have greater completeness. Care should be taken in comparing these cities.

² The Denver Fire Department has jurisdiction over Denver city and county.

³ The total dollar loss per capita for the UFIRS cities excludes Syracuse, which does not record that information, and is based on a population of 2,328,956.

SOURCE: (1) 1975 CFIRS, (2) 1976 NFIRS, (3) 1976 UFIRS, except Kansas City which was May 1975-April 1976.

NOTE: Highest rates in each city group are circled; the lowest are enclosed in rectangles.

50,000 population and less than 25,000.⁶⁶ Also included in the table are data for seven cities in other States. These have populations ranging between 168,000 and 580,000 persons and appear to be comparable in many respects to the six largest Ohio cities.

Overall rates for California and Ohio are also shown in Table 24. The California data file did not identify individual communities and hence was used only in the aggregate.

There is considerable variation among individual cities in Ohio within each group. Some cities are often simultaneously highest in one respect, such as fire rates, and lowest in another, such as injury rates. (The highest rates within each city group have been circled in Table 47, and low rates are enclosed by a rectangle.) Since we do not know how accurate the data are, these comparisons must be taken only as a starting point for understanding problems and identifying sources of solutions. Perhaps the first question for understanding reasons for differences should be, "Is it a data collection artifact or a real world difference?"

Variation of Fire Losses with Community Size

Figure 20 shows a plot of the average fire and fire loss rates for the four different Ohio population groups and also the average for the UFIRS cities. The patterns are strikingly similar to the analogous plots from the NFPA 1974 survey, Figure 3 and Figure 4. The curves for injury and dollar loss rates agree well in both magnitude and shape. The death rate curve has the same U-shape as in the 1974 survey, but with lower values; this is because Ohio's average death rate is well below the national average (see Appendix IV). The principal difference is in the total fire rate. The large Ohio cities and the UFIRS cities have about the same value as in the NFPA survey, but the rates for the remaining Ohio groups are about 40 percent to 50 percent smaller. This is probably due to under-reporting of fires by local communities to the State in NFIRS for the first year.

⁶⁶ Values for the under 25,000 group were obtained by removing cities with greater than 25,000 population from the Ohio data tape. The figures were not obtained by averaging the values obtained from all cities with less than 25,000 population.

Comparison by City of Residential Fire Causes

Table 48 shows the percent of residential fires within eight major cause categories for each Ohio and UFIRS city. To the extent that the data are valid, they suggest problems (and the priorities) local fire prevention programs might address. They also indicate how well cities have been doing relative to various problems, and what areas may not require additional programs.

Table 48 also shows that the top two or three problems (i.e. most frequent causes) vary from city to city. For example, in Cleveland, incendiary, smoking, and "children playing" fires account for over half of all residential fires. In Columbus, as in Cleveland, incendiary and smoking related fires are important, but cooking-related fires are more important than "children playing." In Cincinnati, cooking and smoking dominate with "children playing" a distant third.

In contrast with the larger cities, as the community size becomes smaller, heating fires apparently become progressively more important. For communities under 25,000 population, it is the principal cause of residential fires; cooking is second and electrical distribution third most frequent.

As was done in the previous table, one can also compare the fire rates among the cities. Table 49 indicates those cities, within each population group, having the highest and lowest fire rate for each cause category. Although some cities are consistently higher than others, the leaders in each category tend to vary. It would be useful to see if the cities with low rates for certain causes have prevention programs aimed at those causes; or if they have community characteristics tending to have fewer fires of that type; or if they have reporting practices that would reduce reporting of those fires or report them in another category; or if, in fact, the laws of chance were kind to them that year.

The average fire rates for each cause category versus average community size were previously plotted in Figure 14, page . Except for heating fires, the largest cities on the average have the highest rates. The largest differences occurred in those categories which the analysis in Section IX showed was dominated by behavior problems such as equipment misuse, rather than categories where equipment malfunction dominated.

**Figure 20. FIRE LOSS RATES vs. COMMUNITY SIZE —
Ohio (NFIRS 1976) and UFIRS Cities**

Population Range (1973 estimate)	Over 200,000 Persons	50,000 - 200,000 Persons	25,000 - 50,000 Persons	Less Than 25,000 Persons
Number of Ohio Fire Departments (1976)	6	14	31	1,170 (Approx.)
Percent of Ohio Population (1973 estimate)	23%	10%	9%	58%

¹ Fires/100,000 persons, death/million persons, injuries/million persons, dollar loss per capita. Reported fire incidents do not include all fires attended by fire departments. For the cities and States shown the degree of completeness varies.

² The Denver Fire Department has jurisdiction over Denver city and county.

³ The total residential dollar loss per capita for the UFIRS cities excludes Syracuse, which does not record that information, and is based on a population of 2,328,956.

SOURCE: (1) 1975 CFIRS, (2) 1976 NFIRS, (3) 1976 UFIRS, except Kansas City which was May 1975-April 1976.

NOTE: For each cause, the highest rates in each city group are circled; the lowest are enclosed in rectangles.

Section XI

Causes of Non-Residential Fires

This section discusses the causes of non-residential fires and fire losses for Ohio and California. The first subsection summarizes the results for eight major non-residential structure occupancy classes. This is followed by a detailed breakdown into the more detailed types of properties within each occupancy class.

As is the case for residential fires, it is necessary to identify for each State the property types that have the most fire losses, and their causes, since they vary somewhat from State to State and occupancy to occupancy. Although fire losses for each property type are presented, comparison of relative risk for each was not possible because that would require knowledge of the number of structures or of total property value, which for the most part was not available.

The leading properties and causes are generally the ones where most fire prevention efforts should be placed to achieve further reduction in losses. There are, however, exceptions. The general cost-effectiveness principle is that one should consider investing in programs likely to give the greatest loss reduction per dollar spent.

In interpreting the tables, it should be recalled that many industrial fires attended by industrial fire brigades are not reported to fire departments. Thus, the data here only represent the part of the problem addressed by public agencies.

SUMMARY OF CAUSES OF NON-RESIDENTIAL FIRES

Table 50 summarizes the causes of California and Ohio fires for the eight major 901 non-residential occupancies. Highlights of the table are discussed below.

In both States, incendiary or suspicious fires are by far the principal cause of non-residential fires, injuries, and dollar loss. Electrical distribu-

tion ranks second as the cause of fires and dollar loss.

There are few non-residential fire deaths relative to residential fire deaths in both States. The ones which occurred are distributed across several categories of causes.

The leading cause categories for fires for each major non-residential occupancy type are listed below. The list applies amazingly well both to California and Ohio, adding to the face validity of the results. More than one cause is listed when one alone did not dominate.

Public Assembly	—Cooking (mostly in restaurants); Incendiary or Suspicious
Education	—Incendiary or Suspicious in day schools
Institutions	—Smoking; Incendiary or Suspicious
Stores and Offices	—Incendiary or Suspicious; Electrical Distribution
Basic Industry	—Electrical Distribution (mostly from fires in the power industry)
Manufacturing	—Many assorted causes
Storage	—Incendiary or Suspicious
Vacant, Construction	—Incendiary or Suspicious

Prevention programs should be targeted especially against these causes. It is clear that different problems must be focused on in different types of properties.

DETAILED CHARACTERISTICS OF NON-RESIDENTIAL FIRES

More details on the causes of California and Ohio non-residential occupancy fires are presented in this section. For each occupancy category, some prevention thoughts are presented in

**Table 50. FIRES IN NON-RESIDENTIAL STRUCTURES BY PROPERTY TYPE

the California sections. Since the profiles for Ohio are generally similar, many of the same comments would apply there.

California Fires in Public Assembly Properties

Table 51 shows that eating and drinking establishments (restaurants, taverns, etc.) have over half of the fires and dollar losses among fires in public assembly places. The most common cause of fire in these eating and drinking places is cooking (40 percent), followed by incendiary or suspicious (12 percent), and electrical distribution (10 percent). However, the major dollar losses in public assembly fires are not from the most frequent cause (cooking), but are from incendiary or suspicious fires in eating and drinking places. "Unknown" cause is second for dollar loss, again mainly for eating and drinking places. Electrical distribution fires are third in dollar loss, mainly from fires in theaters.

Further analysis of reasons for cooking fires and types of places having incendiary fires would be desirable. In the meantime, inspectors might emphasize reducing hazards in eatery kitchens and encouraging sprinkler systems. Specifically, it is recommended that emphasis be given to promoting use of grease flues (built to code standards) and encouraging the installation of venthood extinguishers.

Ohio Fires in Public Assembly Properties

As in California, eating and drinking establishments have the most fires in this category, with the leading causes being cooking and incendiary or suspicious. (See Table 52). Dollar loss causes are also similar to California, except that churches sustained a large dollar loss, but theaters did not. Fires of unknown cause have the greatest dollar loss.

California Fires in Educational Properties

Table 53 shows that day schools have most of the fires and dollar loss in educational properties. The principal cause of fires in day schools is incendiary or suspicious (64 percent). Open flame and spark (9 percent) and children playing (4 percent) are next most important.

Substantial dollar loss also results from incendiary or suspicious fires in trade or business

schools. Colleges and boarding schools account for very small parts of the problem.

The net implication is a need to concentrate on—perhaps even shift resources to—educating and apprehending juvenile firesetters. Pinpointing the communities and levels of schools, preferably even the particular schools which account for the bulk of the fires, might be the next steps at the local and State level. Analysis of this detailed data for several years should indicate whether there are isolated "hot spots" or a general problem.

Ohio Fires in Educational Properties

As in California, the leading cause combination for fires and losses is incendiary or suspicious fires in day schools. (See Table 54.) However, electrical distribution fires are important for dollar loss, while children playing and open flame and spark are not. Note that one fire in a boarding school, involving flammable liquids, led to a large dollar loss.

California Fires in Institutional Properties

The two most frequent types of institutional fires are hospital fires of smoking-related origin and prison fires of incendiary origin. (See Table 55.) In fact, smoking and incendiarism account for more than 50 percent of all fires in institutional property. In prisons, these two causes account for 91 percent of the property loss from fires. Homes for the aged are by no means a minor fire problem, but probably are receiving a disproportionate share of publicity relative to where the center of the institutional problem now seems to be.

Increased enforcement of smoking regulations and better fire protection education of staff and residents in institutions may be warranted. Intentionally set fires in prisons can be attacked by using care in selecting materials used in furnishings, by employee vigilance, and by use of automatic detectors.

Ohio Fires in Institutional Properties

As in California, the type of institution with the most fires is hospitals. (See Table 56.) The most frequent cause in hospitals is smoking. Other significant problems in institutions are smoking in homes for the mentally handicapped and incendiary fires in prisons.

California Fires in Store and Office Properties

The occupancies with the most fires in this category are offices, motor vehicle sales places, and food stores. (See Table 57.) For dollar loss, these properties plus household goods stores are important.

The leading cause of fires in stores and offices involved electrical distribution problems, especially in offices and food stores. This is followed closely by incendiary or suspicious fires in offices, food stores, and motor vehicle sales places. For dollar loss, the leading cause is incendiarism. A small number of exposure fires in motor vehicle sales places apparently also caused much loss.

Other frequent situations are appliance fires in professional supply stores and flammable liquids fires in motor vehicle sales property. A small number of heating-related fires in household goods stores are also important for dollar loss.

The prevention focus here needs to be on incendiary fires and electrical distribution fires; the latter might be emphasized during inspection visits.

Ohio Fires in Store and Office Properties

The Ohio properties with the most fires are motor vehicle sales places, followed by food stores and offices, the same top three as in California, though in different order. (See Table 58.) Motor vehicle sales property also ranked first for dollar loss.

The leading cause of fire is incendiary or suspicious (especially in offices, motor vehicle sales, food stores, and household goods stores). Electrical distribution is the second leading cause (especially in offices and motor vehicle sales), but accounts for most dollar loss (especially in hobby and home repair stores).

California Fires in Basic Industry, Utility, and Defense Properties

Half of the fires in this category are electrical distribution fires, primarily in utility and energy distribution properties and in laboratories. (See Table 59.) From the loss viewpoint, the picture is somewhat different. Large losses result from a

small number of incendiary or suspicious fires and electrical distribution fires in agricultural occupancies, and from small numbers of equipment fires in laboratories and communications or defense industries.

Ohio Fires in Basic Industry, Utility, and Defense Properties

There are far fewer fires and much less dollar loss in this category in Ohio than in California. (See Table 60.) Only 96 fires were reported, compared with over 1,200 in California. Electrical distribution is the principal cause of fires in this property class, distributed across many industries. A large dollar loss resulted from incendiary or suspicious fires in mining companies.

California Fires in Manufacturing Properties

The manufacturing property class with the most fires in California is that involved with metals and woods, including furniture, paper, and printing. (See Table 61.) One in six manufacturing fires reported are of unknown cause, by far the largest single cause category. Of the known causes, most involved "other equipment." The cause second in importance is incendiary or suspicious (especially in wood-related manufacturing properties), followed by electrical distribution (from metals manufacturing properties). Dollar losses are concentrated in incendiary fires in food manufacturing, equipment and electrical distribution fires in metal manufacturing, and gas (explosions) in the chemical industry.

Ohio Fires In Manufacturing Properties

As in California, most of the Ohio fires occur in metal manufacturing properties. (See Table 62.) Chemical manufacturing properties, however, lead dollar loss. The principal causes of fire in metals manufacturing involve a variety of "other equipment" (23 percent), as in California, followed by flammable liquids (12 percent), and open flame or spark (9 percent). In wood manufacturing fires, "other equipment" is the most frequent cause, but incendiarism and unknown causes account for most dollar losses. Across all manufacturing property types, relatively few fires of unknown cause are reported, but these by far lead to the largest dollar losses.

California Fires in Storage Properties

Vehicle storage (mostly garages) are the most frequently cited type of storage fires (57 percent). (See Table 63.) Of these, 90 percent are residential garages.⁵⁷ Principal causes of vehicle storage fires are incendiary or suspicious (21 percent), unknown (17 percent), open flame and spark (14 percent), and exposure (14 percent). Of the latter, 85 percent were from residential fires. Incendiary or suspicious was the principal cause of all storage fires. This type of fire led to large losses in vehicle, chemical, and agricultural storages. Large losses also are sustained from fires of unknown causes in agricultural and vehicle storages, and from flammable liquid fires in chemical storage.

Ohio Fires in Storage Properties

As in California, Table 64 shows that vehicle storage is by far the most frequent type of Ohio storage fires (but ranks third in dollar loss). Incendiary/suspicious is the leading cause of vehicle storage fires (32 percent), with "children playing" next in importance (12 percent). Agricultural storage, though a distant second to vehicle storage in number of fires, is the leading category for dollar loss, accounting for 50 percent of storage losses. The principal known cause of these agricultural storage fires is incendiary or suspicious, followed by electrical distribution and natural cause. Dollar loss was highest for fires of unknown cause, both overall and for agricultural storage in particular.

⁵⁷ Residential garages, if detached from the house, are included in this category by NFPA 901 code. Exposure from residential fires accounted for fully 12 percent of all vehicle storage fires. Therefore, many vehicle storage fires are not really non-residential.

California Fires in Mobile Properties

In California (see Table 65), automobiles are by far the leading mobile property in terms of number of fires and fire losses. All other categories account for only one-quarter of mobile property fires. Trucks rank second in the number of fires, while mobile homes "for non-residential use" rank second in dollar loss⁵⁸

The leading cause category by far for automobile fires and fire losses, as well as for overall mobile property, is "flammable liquids" (45 percent). Other frequent causes are unknown (14 percent), electrical distribution (11 percent), and incendiary or suspicious (9 percent). Incendiary fires, although a small fraction of auto fires, account for almost a quarter of the dollar loss from auto fires.

Ohio Fires in Mobile Properties

As in California, automobiles are the most frequent mobile property for fires and fire losses. "Flammable liquids" is the leading cause. (See Table 66.)⁵⁹ A very small number of rail transport fires involving flammable liquids resulted in very large dollar loss, half as much loss as from the more than 10,000 auto fires. This suggests the importance of increased attention to transportation of hazardous materials.

⁵⁸ We do not know how many residential mobile home fires were included accidentally here. That the vast majority of the dollar loss resulted from fires related to home appliances suggests that the category included at least some residential mobile home fires.

⁵⁹ Mobile homes are not included in this property type in this analysis.

¹ Reported fire incidents shown do not include all fires attended by fire departments. Estimated completeness is roughly 90 percent for California.

² "Agriculture" does not include "crops and orchards"; these are included, along with "forests, hunting, fishing" in Outside Fires.

NOTE: Some totals may not equal 100 percent or the sum of their elements due to round-off error. Percentages less than one were rounded to the nearest tenth of a percent.

PART III

Appendices

Appendix I

Fire-Related Activities of the Federal Government

This appendix describes the fire prevention activities of those Federal agencies most actively involved with the fire problem. First, the activities of the Department of Commerce are discussed; then, those of selected other agencies are identified and briefly described. This appendix is not meant to include all fire-related activities of the Federal Government, but rather is meant to illustrate various ongoing fire-related programs.

U.S. DEPARTMENT OF COMMERCE

Two components of the Department of Commerce have a major role in fire safety. They are the National Fire Prevention and Control Administration and the Center for Fire Research in the National Bureau of Standards. Other parts of the Department of Commerce also have specialized fire-related programs. The Maritime Administration is concerned with fire protection of ships and ports. The Economic Development Administration has special concern with the effects of arson on cities.

National Fire Prevention and Control Administration

The National Fire Prevention and Control Administration (NFPCA) was established by Public Law 93-498, the Federal Fire Prevention and Control Act of 1974. That Act followed from a study of the U.S. fire problem by the National Commission on Fire Prevention and Control.⁶⁰ The Commission reported that fire caused an unconscionable loss in lives and property and set a goal of reducing fire losses by 50 percent in the next generation.

NFPCA was set up to assist, supplement, expand, and improve the Nation's fire prevention and control efforts. The Fire Administration has no regulatory or enforcement responsibilities. Most of NFPCA's programs fall under its four major operating areas.

Public Education Office. The PEO is determining the most effective public education programs to improve fire safety and reduce losses. Effectiveness is established by research and identification of success cases. The most effective public education programs are propagated at the State and local levels with assistance from the PEO.

National Academy for Fire Prevention and Control. The National Fire Academy is developing courses to advance professional development in the fire service and fire safety understanding by others engaged in fire protection, such as architects. The Academy emphasizes "training the trainers" who will then return home to train local fire personnel in fire service management, master planning for fire safety, fire investigation, and other areas. The Academy also assists State and local training programs, as well as those colleges and universities offering fire service training.

National Fire Data Center. The Data Center collects, analyzes, and publishes information on the occurrence of fires, deaths, injuries, and losses. The Data Center also provides assistance to State and local governments in setting up their own data systems to be compatible with the National Fire Incident Reporting System. Twenty-two States are now at varying stages of participation in NFIRS, and it is planned to expand the program to include most of the fifty States in the next several years. A reference service is available to answer queries from the fire community and to compile bibliographic materials and abstracts.

⁶⁰ *America Burning: Report of the National Commission on Fire Prevention and Control*, Richard E. Bland, Chairman (Washington, DC: Government Printing Office, 1973).

National Fire Safety and Research Office. The NFSRO coordinates the application of current technology to the fire problem. Some current projects include improving protective equipment for firefighters, evaluating the effectiveness of smoke detectors in residences, and developing master plans for community fire safety.

Center for Fire Research

The Center performs and supports research in all aspects of fire, with the aim of providing scientific and technical knowledge applicable to the prevention and control of fires. This includes efforts in areas such as (1) the fundamental process underlying fires, including physics and chemistry of combustion processes and products, early stages of fires, structural influences in fire behavior, fire-safe design concepts for buildings, and specific fire hazards; (2) biological, physiological, and psychological factors affecting human victims of fire, the performance of individual members of fire services, and the psychological factors leading to arson; and (3) operational tests, demonstration projects, and fire investigations in support of such activities. It also coordinates all activities carried out by the National Bureau of Standards on behalf of the National Fire Prevention and Control Administration.

OTHER FEDERAL AGENCIES INVOLVED IN FIRE SAFETY

Many other agencies of the Federal Government are engaged in fire safety activities related to their sphere of responsibility. They include the Consumer Product Safety Commission; the Department of Housing and Urban Development (e.g. residential building standards); the Department of Health, Education and Welfare (e.g. the National Center for Health Statistics and the Emergency Medical Service Program); the Department of Transportation (e.g. vehicle fires); the Department of Agriculture (e.g. U.S. Forest Service for wildfires and the Rural Development Service for rural fires); and the Department of Justice (e.g. the Law Enforcement Assistance Administration for arson fires).

Tables I-1 thru I-3 give an indication of some additional involvement of the Federal Government with the fire problem. A more complete and detailed listing of Federal agencies involved

in fire safety will be found in the publication, *Federal Fire Strategies: An Intergovernmental Analysis of NFPCA Program Directions*.⁶¹

OTHER FEDERAL AGENCIES WITH FIRE SAFETY PROGRAMS

U.S. Department of Agriculture

- Cooperative State Research Service**—Research on protection of forest land resources against fire. Research on the role of fire in normal usage of farmland. Technical assistance and cost-sharing funds for preventing and suppressing wildfires on State and private lands.
- Forest Service Cooperative Fire Protection**—Research on all aspects of forest fire protection and control.
- Farmer's Home Administration**—Provides insured loans to rural communities for essential community improvements, including fire stations, apparatus, and equipment.
- Rural Development Service**—Provides loans to benefit local communities, including fire protection.

U.S. Department of Health, Education and Welfare

- Center for Disease Control, Public Health Service**—Provides grants for research about hazards in the work environment harmful to the health and safety of workers including fire-related dangers and injuries. Provides grants for training professional personnel in occupational safety and health, including study of potential fire hazards and injuries.
- Health Services Administration, Public Health Service**—Provides grants for planning and development of comprehensive emergency medical services.

U.S. Department of Housing and Urban Development

- Community Planning and Development**—Provides grants to develop viable urban communities, including funds for construction or improvement of fire protection services and facilities.
- Federal Disaster Assistance Administration**—Provides grants for post-disaster repair, restoration, relief, and recovery.
- Federal Insurance Administration**—Provides reinsurance to private insurers participating in Fair Plans.

U.S. Department of Interior

- Bureau of Land Management**—Provides for the protection of 450 million acres of natural lands and

⁶¹ *Federal Fire Strategies: An Intergovernmental Analysis of NFPCA Program Directions*, B. Michael Kahl, Project Director (Yorba Linda, CA: Kahl Associates, Inc. Research Consultant for the National Fire Prevention and Control Administration, June 1977).

their resources and operates the Boise Inter-agency Fire Center.

U.S. Department of Labor

Occupational Safety and Health Administration—
Provides grants to assure safe working conditions, including fire-related hazards.

Manpower Administration—Provides grants to assist in employment and training of public service employees, including the fire service.

U.S. Department of Transportation

National Highway Traffic Safety Administration—
Provides grants and other financial assistance for the purchase of ambulances, rescue trucks, approved equipment, and training for personnel. Administers programs relating to vehicle fires.

Federal Railroad Administration—Provides grants for promotion of safety in railroad operations, including transportation of hazardous materials.

Federal Aviation Administration—Development of adequate public airports, including firefighting and crash rescue equipment. Development of standards for fire-safe and crash-worthy construction and operation of aircraft.

Office of Pipeline Safety—Provides grants to develop and maintain pipeline safety programs. Collects data on pipeline accidents.

National Transportation Safety Board—Investigation of transportation accidents, recommendations for improving transportation safety.

U.S. Department of Treasury

Office of Revenue Sharing—Provides Federal financial aid, which may be allocated to fire protection, to states, countries, cities, and townships.

Small Business Administration—Provides loans and guaranteed/insured loans to assist small businesses likely to suffer substantial loss and injury through compliance with OSHA standards.

Appendix II

Annual Investment in Fire Safety

The magnitude of the annual investment in fire safety is not currently known with any degree of certainty. Table II-1 provides a rough indication of the general magnitude of annual investments in fire safety. Although we do not place high confidence in the total investment cost plus loss estimate as an absolute number, we are confident that the \$13.6 billion figure represents a lower bound and that the true figure, if it were known, probably is considerably higher.

**Table II-1. ROUGH APPROXIMATION
OF ANNUAL INVESTMENT IN
FIRE SAFETY**

Federal fire-related expenditures, including grants and loans	\$ 260,000,000+?
Insurance premiums for fire coverage	4,500,000,000+?
Individual expenses for fire protection equipment	350,000,000+?
Public fire protection	4,200,000,000
Private fire protection organizations	100,000,000
Total investment cost ..	\$ 9,400,000,000+?
Estimated fire losses	4,200,000,000+?
TOTAL INVESTMENT COST PLUS LOSS ..	\$13,600,000,000+?

NOTE: Figures represent lower bounds of the actual values. Those with the "+?" are likely to be more uncertain and represent the general magnitude of the value.

Despite the uncertainty concerning the \$13.6 billion figure, some components of that figure have a more solid basis than others. These include the figures for estimated fire losses and for expenditures by public fire departments and private fire protection organizations.

Insurance premiums paid directly for fire protection are not published by the insurance industry. However, data on premiums for coverage for multiple risks are available. The proportion of that total figure that was attributable to fire protection was estimated subjectively. Consequently, the \$4.5 billion figure should be considered as an indicator of the approximate magnitude and a satisfactory estimate of that cost component.

The figure given for the expenses incurred by individuals for fire protection is the least solidly based. It includes only expenditures for smoke detectors and does not include other cost components. The other missing components (which would include the marginal costs of constructing and maintaining structures in compliance with fire and building codes, for example) most likely are the major portion of this component. The true amount of this cost component and even its order of magnitude is not currently known.

In view of the tentative nature of the above estimates, no attempt was made to treat investment costs in a precise economic manner: for example, to amortize each category of investment according to its expected useful duration.

Appendix III

NFPA 1974 Survey

The analysis of the NFPA 1974 survey data in this section was based upon preliminary tabulations provided by NFPA as part of a 1977 study.⁶² The main feature of the NFPCA analysis of the NFPA data is the formation of overall national estimates based upon stratifying the data according to urban and rural population and, more specifically, according to size of community. The nature of the data and how they were edited and analyzed is described below.

CHARACTERISTICS OF THE DATA

For a number of years, NFPA has conducted an annual survey of local fire departments for information on fires and fire losses. In 1974 over 2,000 questionnaires were mailed to a sample of departments. About 50 percent responded. As is the case for most mail surveys, it is not known whether the self-selection of the respondents introduced any significant bias.⁶³ Some of the original survey data were of questionable validity. To improve the quality of the data used in making the national estimates, NFPA devised an "edit" process to identify and discard inconsistent or otherwise questionable survey responses. Of the approximately 1,000 fire departments responding, the data from about 955 were retained for estimating number of fire incidents, 900 for deaths, 727 for injuries, and 534 for dollar loss. The validity of the results reported here depends in large measure on the degree of success of the data "cleaning" for its new application.

⁶² Derry, Louis, Principal Investigator, *Analysis of NFPA Data for National Fire Loss Estimates* (Boston, MA: National Fire Protection Association 1977), Fire Administration Contract No. 7-34753.

⁶³ This can be tested by a follow-up survey of a sample of non-respondents to the first wave, but obviously costs more and takes more time, and was not done for this report.

DATA SUMMARY

Table III-1 summarizes the fire losses for each of nine groupings of communities by population. Fire and death rates are shown separately for residential and non-residential occupancies. Injuries and dollar loss were presented in total only. Since not all communities gave the occupancy breakdown, the total of the residential and non-residential rates differs slightly from the total when results from communities are added.

The numbers shown in parentheses indicate the statistical uncertainty (or precision) associated with each quantity in the table. The fact that the precision is lowest for the smallest communities is discussed in more detail later.⁶⁴

Column 2 of the table gives the number of community reports in the sample that, after editing, contained satisfactory data on the total number of fires. The sample number of communities usable for other loss categories was almost always much smaller.

Column 4 shows the percent of the U.S. population (for 1970) contained in each population interval. These values were also the weights assigned to each interval in calculating the national estimates. The percentages shown are rough estimates. The Census figures are not exactly applicable since the geographic area covered by a fire department does not always coincide with the political boundaries of "places" used by the Census Bureau. For communities above 10,000 population, the differences are probably not significant. (Exceptions are fire departments which serve counties rather than cities.) The Census Bureau does not provide population size esti-

⁶⁴ As a rough check on the NFPA survey data for the largest cities, data from 1976 was collected directly from New York City, Los Angeles County, Detroit, and Philadelphia; and was found to compare satisfactorily with the 1974 survey.

**Table III-1. FIRE LOSS RATES VERSUS COMMUNITY POPULATION—
NFPA 1974 Survey**

(1) Population Interval	No. F.D.'s In Sample (for total Fires)	Estimated F.D.'s in U.S.	Estimated % of 1970 Popula- tion	RESIDENTIAL		NON-RESIDENTIAL		TOTAL ²			
				Fires (per 10,000)	Deaths (per million)	Fires (per 10,000)	Deaths (per million)	Fires (per 10,000)	Deaths (per million)	Injuries (per million)	Dollar Loss (per person)
METROPOLIS

10,000 to 25,000	190	1,157	10.5%	32.3(±1.1)	33.3(± 5.0)	72.1(± 2.5)	6.3(± 2.1)	103.1(± 3.0)	37.7(± 5.2)	391(±33)	10.60(±1.30)
SMALL TOWNS											
5,000 to 10,000	83	5,199	18.3%	32.1(±2.5)	27.9(± 8.7)	67.7(± 4.9)	3.7(± 2.3)	98.4(± 5.7)	34.9(± 9.2)	218(±50)	17.50(±3.50)
RURAL											
Under 5,000	71	18,140	26.5%	33.2(±3.7)	29.3(±12.9)	85.1(± 8.8)	10.2(±11.2)	119.0(±11.0)	47.8(±19.6)	202(±59)	17.10(±3.30)
TOTAL	955	23,355	100.0%	32.1	28.0	81.4	5.7	113.6	36.7	352	\$14.10

¹ Editing and tabulation of data provided by NFPA; responsibility for synthesis is NFPCA's.

² Residential plus non-residential fire and death rates do not sum exactly to "total," because some fire departments did not report both.

³ Los Angeles County excluded; if included, the rate would be 36.5 per million.

⁴ Rough estimate.

NOTE: Numbers in parentheses represent the precision of each estimated rate, for 68% confidence; doubling these numbers gives 95% confidence.

mates for unincorporated urban areas or for most rural areas. As an approximation, since there is apparently no accurate estimate of the total population encompassed by fire departments serving fewer than 5,000 persons, the total percent of rural population (26.5 percent) was assigned to the 0-5,000 population interval. The remaining unaccounted urban population (18.3 percent), mostly unincorporated areas, was assigned to the 5,000-10,000 interval.

The number of fire departments in each interval, shown in column 3, is not used directly in the computations. These numbers do not reflect the fact that many fire departments protect the area of other jurisdictions in addition to their own area. The number of departments in each interval was obtained from NFPCA's mailing list and corresponds reasonably well with Census's count of "places" in each of the population intervals greater than 10,000. The number of departments in each of the last two population intervals represents rough estimates.

ANALYSIS

Plots of total fires, deaths, injuries, and dollar loss versus population of community appear in Figure 3, page 17. Figure III-1 is a plot of fire incident and death rates for residential and non-residential occupancies. The vertical lines show the statistical precision (or confidence interval) associated with each of the plotted values. The patterns exhibited by each of the curves in Figure III-1 differ considerably. The main features are summarized below.

Residential Fire Death Rates

The residential fire death rate pattern of Figure III-1 is roughly U-shaped. The highest residential death rate (37 per million) occurs for the very large cities. The lowest (17 per million) occurs for medium sized cities (population 50,000-100,000). The three smallest population intervals (those below 25,000 population) also have high death rates (28-33 per million). However, the small town/rural estimates have low precision, being based upon a total of only 100, 15, and 6 deaths, respectively, in each interval.

Some insights as to why the residential fire death rate pattern is U-shaped are given by Figure

III-2. The pattern in the death rate for all fires closely follows the pattern in the death rate for fires in one and two family dwellings. The trough of both curves occurs in communities of medium population size.

As would be expected, large cities have a higher rate of deaths from apartment fires than the less populous areas do, whereas the smaller and rural areas have a higher rate of death from fires in mobile homes.

The death rate of fires in hotels and motels is relatively constant over all population intervals.

Non-Residential Fire Death Rates

The non-residential death rate of Figure III-1 is much less than the residential fire death rate for each population interval. The pattern is also different. The rates are approximately constant, or increase slightly as population decreases in communities of more than 5,000 population. But for rural communities, the non-residential fire death rate increases considerably. This estimate has extremely low precision, being based only on 2 deaths from a single nursing home fire. Until more extensive rural data become available, one cannot really assert that the observed difference is real rather than being merely a random effect.⁶⁵

Death Rate for All Fires

The fire death rates (shown in Figure 6, page 22) for residential and non-residential fires combined are similar to the curve for residential alone. The precision of the estimate of the total death rate for each population interval is given in Table III-2. Note that because of the low precision of the rural estimate (± 41 percent), the value is not statistically significantly greater than the values given for the two next larger population intervals.

The incident rates for residential fires show only moderate variation. They are highest for the very large cities and lowest for cities between 50,000 and 100,000 population. Below 50,000 the rate is approximately constant. This behavior is quite different from that found in the NFIRS data for Ohio communities (Figure 20, page 107), which show a sharp fall-off for communities below

⁶⁵ Statistically, the observed rural death rate is not significantly larger, since the confidence limits overlap so much with those from the preceding population interval.

Figure III-1. FIRE AND DEATH RATES vs. COMMUNITY POPULATION – 1974 NFPA Survey

	Metro-polis	Large Cities			Medium Cities	Small Cities		Small Towns	Rural
Population Range	Over 1 Million	500,000-Million	250,000-500,000	100,000-250,000	50,000-100,000	25,000-50,000	10,000-25,000	5,000-10,000	Under 5,000
Approximate Number of Fire Departments	6	25	30	95	227	476	1,157	5,200	18,140
Approximate Percent of U.S. Population	9.2%	6.4%	5.1%	7%	8.2%	8.8%	10.5%	18.3%	26.5%

¹ Rough estimate.

NOTE: Vertical lines denote precision of estimate (the distance from the midpoint to the end of the line is one standard deviation). The National Averages plotted are those developed from the NFPA Survey results.

All Communities	32.1 (±1.1)	28.0 (± 4.0)	81.4 (±2.7)	5.7 (± 3.0)	113.6 (± 3.3)	36.7 (± 3.5)	352 (±19)	\$14.10 (±1.20)
RELATIVE PRECISION ¹ (%)								
URBAN (Cities > 10,000)	2.0%	7.3%	2.3%	11.6%	1.9%	4.4%	2.6%	3.7%
URBAN (Cities > 5,000)	2.5%	9.8%	2.4%	17.1%	2.0%	7.6%	3.7%	8.1%
RURAL (Communities < 5,000)	11.0%	44.0%	10.3%	100.0%	9.2%	41.0%	29.2%	19.3%
All Communities	3.5%	14.1%	3.3%	52.5%	2.9%	9.4%	5.5%	8.6%

¹ Limits shown in parentheses are for 68% confidence; doubling the limits gives 95% confidence.

² No satisfactory data from cities greater than one million population was available.

NOTE: Numbers in parentheses represent the precision of each estimated rate for 68% confidence; doubling these numbers gives 95% confidence.

Figure 19. FIRES BY MONTH OF YEAR, ALL OCCUPANCY TYPES — Ohio (NFIRS 1976)

¹ Nationwide fatality data from the National Center for Health Statistics in dotted lines show a similar pattern, though not as extreme. Based on 1974 fire and burn deaths as reported in *Accident Facts, 1976*, National Safety Council, p. 15.

² Losses of \$1,000 or more.

SOURCE: Ohio 1976 NFIRS data, except as noted.

200,000 population. Ohio's rate for its largest cities (200,000-700,000 population) was 28 per 10,000 persons, only slightly less than the values in Figure III-1. But for communities below 200,000 population, the Ohio rates (11-15) are only one-third to one-half of the survey values. The most likely explanation is that the Ohio NFIRS reporting from small communities was more incomplete than that from larger communities in this first year of NFIRS. We will explore this inconsistency further.

Non-Residential Fire Incident Rate

The incident rates of non-residential fires are extremely high for very large cities and sharply decrease with population size at approximately

a constant rate, except for the rural population category where the rate (which again is imprecisely estimated) increases sharply. The reasons for this behavior of the urban and rural communities will also be explored in the future.

Total Fire Incident Rate

Because residential fires constitute a relatively small proportion of total fires, the total fire incident rate (Figure 20, page 107) is similar to the curve for non-residential fires alone.

Total Injury and Loss Rates

As noted previously, the NFPA 1974 survey data on injuries were not broken down by occupancy.

The data are probably not too reliable because of widely differing practices among communities. The reasons for the observed patterns for total injury rate and total dollar loss rate (Figure 4 of Part I) are not known. Future analysis of the dollar loss broken down by occupancy could give insight to this aspect of the problem.

EXTRAPOLATION TO NATIONAL ESTIMATES

Assuming that the data in Table III-1 represent a random sample stratified according to population size, the overall national estimates (or stratified means) are simply the weighted average of the rates for each population interval. The weights correspond to the percent of total U.S. population shown in Table III-1. The precision of the estimates is readily computed using formulas in the theory of random stratified sampling.⁶⁶ Because of the large uncertainties associated with the rural data, separate urban and rural estimates have been developed. The urban estimate has also been computed with small towns omitted, that is with cities greater than 10,000 in population.

The results of the statistical calculations are summarized in Table III-2. The lower portion of the table shows the relative precision (in percent) of each estimate. A brief summary of the principal estimates based on the NFPA survey data is given below.

⁶⁶ The overall precision equals the square root of the sum of weighted squares of the individual precisions for each interval (shown in parentheses in Table III-1). A 68 percent confidence level is associated with the resulting value. For 95 percent confidence the precision value should be doubled.

Fires

The estimate of the U.S. total fire rate based on the survey is 113.6 ± 3.3 per 10,000 persons. The urban rate is 111.7 ± 2.2 , the rural rate 119.0 ± 11.0 . Residential fires account for 28 percent of all fires, both urban and rural.

Deaths

The estimate of the U.S. total fire death rate based on the survey is 36.7 ± 3.5 per million persons. The urban rate is 32.7 ± 2.5 , the rural rate 47.8 ± 19.6 . Urban residential deaths account for 87 percent of total urban fire deaths; rural residential deaths account for 74 percent of total rural fire deaths.

Injuries

The estimate of the U.S. total fire injury rate based on the survey is 352 ± 19 per million. The urban rate is 406 ± 15 , the rural rate 202 ± 59 .

Dollar Loss

The estimate of the U.S. total dollar loss from fire per capita based on the survey is \$14.10 ± 1.20 . The urban rate is \$12.80 ± 1.00 , the rural rate \$17.10 ± 3.30 .

It is apparent from Table III-2 that a larger rural survey sample would greatly improve the overall precision of the national estimate. Special problems could be anticipated in such a survey, since almost all rural departments are manned by volunteers not likely to be intimately familiar with 901 codes, partly because the vast majority of such departments experience no deaths and relatively few fires and injuries each year and therefore are not experienced in filling out forms.

Appendix IV

State Fire Marshal Data

The analysis of the State Fire Marshal data in this section assesses its suitability for developing estimates of the national fire loss. This appendix discusses the data limitations, provides a summary of this information, extrapolates from it to produce national estimates, and compares the death rates derived from State Fire Marshal data with those derived from NCHS death certificate data.⁶⁷

As a result of this assessment, it was concluded that the uncertainty regarding the completeness of reporting is sufficiently large that this data source cannot be used by itself in making national estimates of the fire incident rate. This data source must also be supplemented for estimates of other aspects of the fire problem because of differences in the basic definitions and techniques used.

DATA LIMITATIONS

Fire losses contained in State Fire Marshal reports from 34 States plus the District of Columbia are analyzed below. The remaining 16 States either issued no reports or copies were not available.

Data collection systems for the States differ considerably. Some are quite sophisticated and are organized on a statewide basis (e.g. an NFIRS-type system). Most States simply compile the data reported by local fire departments, which are free to adopt whatever system they wish. Both the criteria for reporting a fire and the definitions of different classes of fires differ among States, and sometimes among communities within the same State. A few States report only those fires having detailed investigations or only those fires exceed-

ing a certain dollar loss or involving an injury or death. Also, many States do not summarize fires according to residential or non-residential occupancy categories.

Almost all States have some degree of under-reporting of incidents by local departments to the State, even when reporting by local fire departments is mandatory and when there is a payment made for each report received. This under-reporting is believed to be substantial in regard to total number of fires, but much less so for deaths.

Reporting of injuries and property loss is also not consistent among States. Minor injuries, which comprise a substantial proportion of the total, often are unreported. Likewise, the quality of dollar estimates of property loss depends strongly on the knowledge and experience of the estimator. In addition, local conventions differ in regard to what costing criteria to use—replacement, market, or book value.

As was the case for local communities, even after allowing for reporting differences, there is still considerable variation in fire and death rates among the States. This variation probably reflects, in part, the differences in climatic and socioeconomic conditions among the States and, in part, differences in fire safety performance. The rationale for treating population size as a stratifying variable is not as relevant as it was for local communities. However, the smaller the State the larger will be the random fluctuation in fire losses from year to year.

DATA SUMMARY

The State Fire Marshal data on fire incident and death rates are summarized in Table IV-1; injuries and dollar loss in Table IV-2. The data for about one-third of the States are for 1976 and

⁶⁷ After the analysis of the State Fire Marshal data had been completed, tapes of NCHS death data for 1974 and 1975 became available. A summary of the NCHS data and comparison with the State data is given on page . Preliminary tabulations of these NCHS data indicate that several States, primarily those with low death rates, may have underestimated their fire deaths.

Table IV-1. SUMMARY OF STATE FIRE AND DEATH RATES
—State Fire Marshal Reports¹

State	Year	Residential		Non-Residential		Total	
(According to Increasing Total Death Rate)		Fires (per 10,000)	Deaths (per million)	Fires (per 10,000)	Deaths (per million)	Fires (per 10,000)	Deaths (per million)

¹ Numbers in parentheses show increase or decrease from previous year.

² These States did not report injuries or dollar losses. They are included here to preserve the relative ranking by death rate.

³ Illinois data excludes Chicago.

about two-thirds for 1975; Arizona and Wyoming are for 1974. The States are listed according to increasing total death rate. The numbers in parentheses represent the change from the previous year, with an asterisk denoting when the change is not statistically significant; that is, it is probably due to chance.

The frequency distributions for fire incident and death rates are plotted in Figures IV-1 and IV-2. For fire incident rates, almost one-third of the States are seen to have exceptionally low values. Of these, Missouri and Iowa reporting is apparently quite complete; Vermont and North Dakota report only fires with loss exceeding \$200 and \$25, respectively; and in Kansas 25 of 103 counties do not report. The situation in Minnesota, Kentucky, Nebraska, and West Virginia has not been determined. The remaining portion of the frequency distribution (except for Nevada) shows statistical regularity; however, the fire

rates are on the average only about two-thirds of the rates in the NFPA survey.

In Figure IV-1 we have sketched, using subjective judgment based on the NFPA survey estimates in the previous section as a guide, the frequency distribution one might expect to find if there had been 100 percent reporting of all fires by all States. It seems clear that the uncertainty regarding completeness of reporting is so great that the State fire incident rate data are not suitable for making national estimates at present.

The frequency distribution for fire death rates in Figure IV-2 is much more regular. Fewer States have low death rates, indicating that under-reporting of deaths probably is less of a problem than for fires.

Data on fire injuries were available only for 16 States. On the average one would expect injuries to correlate with deaths, with injuries being roughly 10-15 times greater. However, the rank-

Figure IV-1. FREQUENCY DISTRIBUTION OF STATE FIRE INCIDENT RATES — State Fire Marshal Reports

**Figure IV-2. FREQUENCY DISTRIBUTION
OF STATE FIRE DEATH RATES —
State Fire Marshal Reports**

ing of injury rates in Table IV-2 is seen to depart considerably from the ranking of death rates. The highest injury rate, for the District of Columbia, exceeded 1,000 per million persons, yielding an injury-to-death ratio of 26. Nevada had the second highest injury rate (and the second lowest death rate) with an injury-to-death ratio exceeding 40. The next largest injury rate was Oregon with an injury-to-death ratio of 12.8. Oregon is often considered by many to have one of the most complete fire reporting systems in the country, which may account for its relatively high reported injury rate.

Dollar loss also shows considerable variability, ranging from \$2 per capita for Delaware and \$5.70 for North Carolina, to \$79.50 for Alaska and \$28.40 for Illinois (excluding Chicago).

Because much of the injury and property loss data seem to be of low quality, statistical plots have not been made for them.

The frequency distributions of the magnitude and direction of the change in fire and death rates for each State (the value shown in parentheses in Table IV-1) are plotted in Figures IV-3 and IV-4. These distributions appear to be fairly well behaved statistically and, as expected, have less variability than the absolute distributions in the previous Figures IV-1 and IV-2.

EXTRAPOLATION TO NATIONAL ESTIMATES

Using the State Fire Marshal data, we developed national estimates by calculating the mean, weighted by population, of the values for individual States. In extrapolating this result to the entire country, the assumption was made that the 35 States (or less, depending on the category) constitute a random (or representative) sample of all States, which may or may not be true.

**Figure IV-3. FREQUENCY DISTRIBUTION OF
YEAR-TO-YEAR CHANGE IN FIRE INCIDENT RATE —
State Fire Marshal Reports**

The results of the statistical calculations are summarized in Table IV-3. The upper half of that table pertains to the magnitude of fire loss while the lower half pertains to change from the previous year. The first column indicates the number of States for which data were available. In some instances the extreme values were not used, either because of suspected significantly large under-reporting or some other special circumstances; the States omitted are noted in the last column.

The second column shows the weighted mean, which corresponds to the national estimate. Since not all States provided a breakdown into residential and non-residential occupancies, the sum of the separate estimates for these occupancies may not always equal the total estimate.

The third column presents the standard deviation, a statistical measure for degree of spread

among the individual values. Differences in population size among States were not taken into account so that the variability reflects both the random fluctuation (principally of the smaller States) as well as differences in State characteristics and fire protection. The last column presents the statistical error attached to the estimate of the mean. This quantity does not take account of any bias resulting from under-reporting.

The mean death rate of 29.5 from these State Fire Marshal reports is somewhat less than the rate of 37 previously obtained from the 1974 NFPA survey or the value of 35 obtained from the HEW National Center for Health Statistics data, which is discussed in the next section. Possible reasons for this low estimate are currently under investigation. The sampling error (or statistical precision, with confidence 68 percent) of the death rate is 4 percent. The error arises from the

**Figure IV-4. FREQUENCY DISTRIBUTION OF
YEAR-TO-YEAR CHANGE IN FIRE DEATH RATE —
State Fire Marshal Reports**

fact that only a (random) sample, 35 out of 50 States and the District of Columbia, is used.

For the 14 States giving residential death data, the mean residential death rate is 18.7 per million persons and the mean non-residential death rate is 7.3 per million persons. The percentage of deaths that are residential is 72 percent, somewhat less than the 83 percent obtained from the NFPA survey. As noted previously, because not all States reported residential deaths separately, the sum of the residential and non-residential rates does not equal the total calculated rate.

As indicated in Figure IV-1, in determining the mean fire rate, we have excluded the 9 States having a total fire rate of less than 20 per 10,000 persons, for which the under-reporting is in most cases likely to be substantial, and Nevada. For the remaining 20 States, the mean fire rate is 79. Of this, 25 percent is residential, which is again

less than the estimate from the NFPA survey (28 percent). The precision of the total fire rate estimate, again ignoring under-reporting bias, is 9 percent. Note that only 6 of the 29 reporting States have total fire rates exceeding 114, the mean from the NFPA survey.

The injury rate, with the District of Columbia excluded, is estimated at 253 per million persons (much below the 1974 NFPA survey estimates), with a precision of 11 percent. The average dollar loss rate, calculated from 16 States (with 13 States omitted) is \$14 per person, the same as for the 1974 survey.

The estimates of annual change shown in the lower half of Table IV-3 show an increase in all categories of fire loss. But taking into account the (absolute) precision in the last column, only the death rate increase is statistically significant. This result for death rates contradicts that obtained

Table IV-3. SUMMARY OF STATISTICAL MEASURES FOR STATE FIRE LOSS ESTIMATES—State Fire Marshal Reports

MAGNITUDE OF CHANGE							
		States With Data	States Used in Calculation	Weighted Mean ¹ (National Estimate)	Standard Deviation	Relative ² Precision(%)	States Omitted from the Calculation

 Values correspond to the 68 percent confidence level.

from the NCHS data in the next section. It is suspected that the increase may be a data artifact reflecting the fact that data reporting is becoming more complete.

COMPARISON OF STATE FIRE MARSHAL AND NATIONAL CENTER FOR HEALTH STATISTICS DEATH DATA

National Center for Health Statistics data tapes on U.S. deaths for 1974 and 1975 were obtained by NFPCA. The fire death rates for the two years for individual States are shown in Table IV-4. Also shown for comparison are the fire death rates for 1974 and 1975 obtained from State Fire Marshal (SFM) reports, if these figures were available.

The total death count from the preliminary tabulation of the NCHS data for all States, 6,746 for 1974 and 6,541 for 1975, is between 950 and 975 (or 13 percent) less than the *adjusted* NCHS total which includes transportation fire deaths. (See Table V-1 in the following Appendix.) Thus, those States which achieve a fairly complete count

are likely to show more deaths than reported by NCHS. Table IV-4 shows that during 1975 death rates obtained from State Fire Marshal reports for 19 States were lower than the NCHS tabulation. For 11 States the SFM rates were higher than NCHS, as would be expected if motor vehicle fire deaths were counted in these reports.

Since neither the SFM data nor the NCHS data **are likely to overestimate** the number of deaths, it seems likely that the better estimation procedure is to choose the larger of the two death rates. That is, both sources are more likely to miss a fire death than to count as a fire death one that is not. One exception to this is that State Fire Marshal data may be counting fatalities as fire deaths in cases where vehicle accidents are accompanied by fire, but it is uncertain whether the original impact or the subsequent fire caused the death. The procedure of choosing the average of the maximum of the NCHS and SFM rates within each year was followed in drawing the map of State death rates and in identifying those States with highest and lowest death rates (Figure 1 and Table 4 of Part I).

Table IV-4. COMPARISON BETWEEN DEATH RATES FROM STATE FIRE MARSHAL REPORTS AND NCHS—Continued

States	1974			1975			Average of Maximum Rate Within Each Year ⁴
	Population ¹	NCHS Rate ²	SFM Rate ³	Population ¹	NCHS Rate ³	SFM Rate ³	
Alabama	3,575,000	42.8	43.1	3,614,000	44.8	39.6	44.0
Alaska	330,000	124.2	136.4	352,000	73.9	88.1	112.3

¹ July 1, 1974, and July 1, 1975 Census population estimates as reported in *Statistical Abstract of the United States, 1976 (97th Ed.)* (Washington, DC: Government Printing Office, 1976), p. 11.

² Deaths per million. NCHS data includes the following ICDA (International Classification of Disease, Adapted for Use in the United States) codes: fires in railway accidents (E803), fires in water transport (E837), accidents caused by fires/flames (E890-899), accidents caused by gas cylinder explosions (E921.1), accidents caused by pressure vessel explosions (E921.8), accidents caused by explosive materials (E923), and late effect of accidents caused by fire (E944).

³ Deaths per million.

⁴ Computed as follows: $[\max(1974 \text{ NCHS}, 1974 \text{ SFM}) + \max(1975 \text{ NCHS}, 1975 \text{ SFM})] \div 2$. These death rates were used in the map (Figure 1), except for New York State where the estimate of 36.7 deaths per million from the 1974 NFPA Survey was used.

⁵ Rate is based on State Fire Marshal data reported by fiscal year.

⁶ Actual average of the maximum rates, which may be less than this value, could not be computed because the State Fire Marshal data is reported by fiscal year. It does appear that the majority of Vermont fire deaths for FY 75 occurred in the first half of 1975.

Appendix V

National Center for Health Statistics Data: The Basis for the NFPCA National Fire Death Estimates

This appendix discusses the basis for arriving at the NFPCA national estimate of fire deaths. The estimate is derived primarily from fire death data published annually by the National Center for Health Statistics (NCHS) of HEW, after certain modifications are made to include a few categories of fire deaths not explicitly identified by NCHS as resulting from fire. The nature and magnitude of these adjustments are discussed in detail here.

The NCHS death data is obtained from death certificates submitted by the 50 States and is believed by NCHS to be over 99 percent complete. These certificates usually indicate whether the death was caused by fire. However, in the case of death from transportation accidents (except water transport), NCHS does not separate fire deaths from non-fire deaths. Thus, some adjustment in the NCHS data is required.

In addition, death certificates of fire victims who expired some time after the fire may not state fire as the underlying cause of death. An adjustment for these omissions is also needed.

The numerical adjustments that were made are based upon a detailed NFPCA study by Fristrom of national fire death data from various sources, including NCHS.⁶⁸ That study gave estimates in terms of minimum and maximum values. Here we suggest intermediate "best estimates," usually but not always the average of these extremes. These are shown in Table V-1.

The principal correction is for motor vehicle fire deaths. Numerous studies of such deaths have been made, yielding widely differing esti-

mates. Table V-2, taken from the Fristrom report, lists the principal studies and their estimates of the percentage of vehicle accident deaths attributed to fire. The values range from 0.6 percent to 7.8 percent. The median of 1.5 percent yields the estimated number of motor vehicle fire deaths labeled as Method A in Table V-1.

Fristrom also examined State Fire Marshal reports and found that, "on the average, 10.8 percent of total fire deaths in the years 1970-1974 could be attributed to fire associated with motor vehicles."⁶⁹ This value results in a slightly larger estimated number of motor vehicle fire deaths, designated in Table V-1 as Method B.

The average of Methods A and B is used in forming the overall NCHS-adjusted national estimates for 1973-1975 shown in the bottom lines of the table. The death rate (35 per million for 1975) is, as noted previously, somewhat greater than was obtained from the State Fire Marshal data (29.5). This result is not surprising for the following reasons.

1. When death results from clothing ignition not accompanied by (uncontrolled) fire, the person affected often is taken directly to the hospital without the knowledge of the local fire department, and thus the death is not reported to the State Fire Marshal.
2. Seriously injured persons may subsequently die without notification to the fire department, and again the death will not be reported to the State.

⁶⁸ Fristrom, Geraldine, *Fire Deaths in the United States: Review of Data Sources and Range of Estimates* (Washington, DC: National Fire Prevention and Control Administration, September 1977).

**Table V-1. CALCULATION OF NFPCA's BEST ESTIMATE OF FIRE DEATHS
(Based on Corrections to HEW Fire Mortality Data)**

	1973	1974	1975	Estimated Range ¹ for Corrections Maximum/Minimum		Correction Rationale ²
NCHS Total	7,080	6,746	6,541			
Estimated corrections for deaths involving:				(Percent of Fire Deaths)		
Rail	+5	+5	+4	1.2%	0 %	For both rail and air, maximum values correspond to DOT's 1973 rate estimates. We arbitrarily used one-half these rates since some detailed studies showed that, although all fatalities in some crashes were recorded as fire deaths, only a fraction were actually fire victims.
Air	+58	+59	+54	6.9%	0 %	
Motor vehicles						
Method A	+680	+563	+555	7.8%	0.6%	Estimate is 1.5% of vehicle-occupant accident deaths. This is the median of 17 studies (Table V-2). It is also the U. of Michigan HSRI recommendation, and the value calculated from <i>NFPA Fire Protection Handbook</i> .
Method B	+860	+818	+793	—	—	State Fire Marshal Reports classify 10.8% of annual fire deaths as motor vehicle fire deaths; this factor is used here.
Delayed reporting of death which is not properly attributed to fire	+231	+220	+213	4-9%	0 %	Estimate is 3.25% of deaths derived as follows: Half of the deaths occurring 2 or more weeks after fire are assumed not to show fire as underlying cause. The maximum number of such delayed deaths is estimated to be $(4+9)/2=6.5\%$ of total annual fire deaths; the minimum is estimated to be 0. The mean value between 6.5% and 0 is 3.25%, and was selected as the factor.
National Estimate ³	8200	7720	7490			
Death rate per million	38.9	36.5	35.1			

¹ For discussion of these ranges see: Fristrom, Geraldine, *Fire Deaths in the United States: Review of Data Sources and Range of Estimates* (Washington, DC: National Fire Prevention and Control Administration, September 1977).

² Includes deaths by: fire and flames, explosion, fire or burning in water transport, accidents caused by explosive materials, and explosions of pressure vessels excluding boilers.

³ Average of Method A and Method B used for motor vehicle fire deaths. Final values for National Estimates rounded to one significant digit.

3. Many motor vehicle fire deaths are believed to go unreported even when the fire was clearly the cause of death. (On the other hand, the cause of death may be wrongly attributed to an accompanying fire, which an autopsy later shows was not the true cause.)

4. Some aircraft fire deaths may not be re-

ported by any local fire department because they occur in areas serviced by private or government fire brigades, or they occur in areas not serviced by any fire protection service.

5. State Fire Marshals do not always get reports of all fire deaths from all departments throughout the State.

Appendix VI

Estimating Precision of Fire Incidents and Fire Casualties

Fires rates, injuries, deaths, and dollar loss fluctuate from one year to the next. The smaller the community and the fewer the number of fires or deaths, the greater is this fluctuation. This randomness is inherent in fire data and should be explicitly taken into account in any interpretations.

The rule for determining the expected random fluctuation over time (or, in statistical jargon, the precision of the estimate) is as follows: The absolute variability (standard deviation) associated with the observed count of fires (or deaths, or injuries) equals the square root of the count. The relative precision (coefficient of variation) in percent equals 100 percent divided by the square root of the observed count.⁷⁰

The relative precision is usually more pertinent than the absolute variability since it applies to per capita rates as well as to actual counts.

Some useful benchmarks are:

Count (e.g. number of deaths)	Relative Precision
4	50%
9	33
16	25
25	20
44	15
100	10
400	5

For example, if a community experienced 25 deaths during the year, the relative precision is 20 percent ($= 100\% \div \sqrt{25}$). This can be inter-

⁷⁰ Statistically, individual counts are assumed to occur randomly following the Poisson distribution for rare events, for which the standard deviation equals the square root of the mean. This distribution does not apply to dollar loss. Also, multiple (exposure) fires and multiple deaths and injuries are assumed to constitute a small fraction of the total. The square root formula usually leads to values that are slightly low since other important random factors (e.g. changes in yearly temperature profile) will increase the fluctuation.

preted as follows: If over an extended period of time with stable (no trend) conditions, a city experiences an average of 25 deaths per year, the chances are 68 percent (or the odds are about 2 to 1) that if the fire situation does not change, the next year will show between 20 and 30 deaths ($= 25 \pm \sqrt{25}$ or $\pm 20\% \times 25$). For 95 percent chance (odds of 19 to 1) the interval should be doubled, giving 25 ± 10 .⁷¹

The low precision associated with small counts is important even for large cities. If too fine a subdivision of the data is used (e.g. fire caused by toasters), the precision will be too low to monitor trends, with statistical confidence, on a yearly basis. For a small community, even the total aggregated count for all fires or deaths may be too imprecise to conclude that a change is statistically significant. Increased precision can be obtained only by monitoring for longer than a year or by combining with data from neighboring communities.

The above rule can be adapted to provide trend charts (similar to quality control charts widely used in industrial production) for monitoring progress over several years. The two numerical examples in Figure VI-1 illustrates the construction of trend charts. The first example shows number of annual fire deaths for Hawaii, according to NCHS statistics, for the years 1971 to 1975. The "quality control" 68 percent limits of ± 2.8 (and 95 percent limits of ± 5.6) are based upon the five-year average of 7.8 deaths per year. If 1976 falls outside the limits, one can conclude (with confidence 68 percent, or 95 percent, as selected) that there has been a statistically significant change.

⁷¹ If the city's population has changed significantly during the period, the procedures for calculation of the mean and of the confidence limits require slight modification.

Figure VI-1. EXAMPLES OF QUALITY CONTROL CHARTS FOR NUMBER OF FIRE DEATHS

The example also indicates how well the square root formula applies to the data. Ideally, the 68 percent limits should include 68 percent of the points and the 95 percent limits should include 95 percent of the points. Actually, three out of five years (60 percent) fall within the 68 percent limits, but only four out of five years (80 percent) are within the 95 percent limits. (The low 1972

value was just barely outside the band.) Considering the complexity of the fire phenomenon, the agreement is amazingly good and more than adequate for practical application.

The second example in Figure VI-1, for Connecticut, also shows very good agreement, with the actual values being slightly outside the calculated limits.

¹ Estimated completeness is on the order of 90 percent for California and 50 percent for Ohio (Reference 1).

² Includes electric blankets, steam irons and other appliances producing controlled heat. Portable cooking equipment contained in Table X-1.

³ Includes vacuum cleaners, motors, generators, electric hand tools, portable appliances not producing heat, and unknown equipment.

⁴ Reported fire incidents shown do not include all fires attended by fire departments.

NOTE: Dollar loss totals may not equal the sum of their elements due to round-off error.

Madison, WI	168,432 (75)	67	39	17	25	8	15

¹ Reported fire incidents shown do not include all fires attended by fire departments. Estimated completeness is on the order of 90 percent for California, 50 percent for Ohio (Reference 11). For the cities shown the degree of completeness may vary from one population group to another. Care should be taken in comparing these cities.

² The Denver Fire Department has jurisdiction over Denver city and county.

³ The total dollar loss per capita for the UFIRS cities excludes Syracuse, which does not record that information, and is based on a population of 2,328,956.

SOURCE: (1) 1975 CFIRS, (2) 1976 NFIRS, (3) 1976 UFIRS, except Kansas City (May 1975-April 1976).

Glossary of Selected Terms Used in This Report

Death rates are the deaths per year per 1,000-000 resident population in each category. For example, the "female death rate" is the total number of females killed each year per 1,000,000 females in the population.

Fatalities include immediate deaths connected with a fire and injuries which became fatalities within one year as a result of a fire.

Fire is the occurrence of an uncontrolled, destructive or explosive burning, regardless of whether it is reported to a fire department or not, or is brought under control prior to the arrival of a fire department. Thus, "false alarms" are not considered fires, while small fires with no injury or little property loss are included.

Injury is physical damage to an individual which is the direct result of a fire and which requires (or should require) professional medical treatment

within one year of the incident, or which results in at least one day of restricted activity immediately following the incident. Injuries to firefighters are included unless specifically noted as being omitted.

Injury rates are the injuries per 1,000,000 resident population in each category unless otherwise noted.

Structures are any assembly of materials forming a construction for occupancy or use. Buildings, bridges, and open platforms are all forms of a structure.

Direct dollar loss is the dollar value of physical damage to property (structure and contents) as a result of a fire. Medical and other indirect costs are excluded.

Fire casualty is a person injured or killed as a direct result of a fire.

Table 14. "CAUSE" CATEGORIES USED IN THIS REPORT

Sorting Sequence	"Cause" Category ¹	Definition
1	Exposure	Caused by heat spreading from another hostile fire.
2	Natural Source	Caused by sun's heat, spontaneous ignition, or chemical, lightning, or static discharge.
3	Incendiary/Suspicious	Fire deliberately set or suspicious circumstances.
4	Explosives, Fireworks	Self-evident; explosives used as incendiary devices included in category 3.
5	Smoking	Cigarettes, cigars, pipes as heat of ignition.
6	Children Playing	Includes all fires caused by children playing with any materials contained in the categories below.
7	Heating Systems	Includes central heating, fixed and portable local heating units, fireplaces and chimneys, water heaters as source of heat.
8	Cooking Equipment	Includes stoves, ovens, fixed and portable warming units, deep fat fryers, open fired grills as source of heat.
9	Air Conditioning, Refrigeration	Includes dehumidifiers and water cooling devices as well as all air conditioning and refrigeration equipment as source of heat.
10	Electrical Distribution	Includes wiring, transformers, meter boxes, power switching gear, outlets, cords, plugs, lighting fixtures as source of heat.
11	Appliances	Includes TV's, radios, phonographs, dryers, washing machines, vacuum cleaners, separate motors, hand tools, electric blankets, irons, electric razors, can openers as heat source.
12	Gas	Material first ignited was a gas: natural, LP, manufactured, anesthetic, acetylene, other gas.
13	Flammable, Combustible Liquid ²	Material first ignited was flammable liquid: gasoline, ethyl alcohol, ethyl ether, acetone, jet fuel, turpentine, kerosene, diesel fuel, cooking oil, lubricating oil, etc.
14	Open Flame, Spark (Heat from)	Includes torches, candles, matches, lighters, open fire, back-fire from internal combustion engine as source of heat.
15	Other Equipment	Includes special equipment (radar, X-ray, computer, telephone, transmitters, vending machine, office machine, pumps, printing press), processing equipment (furnace, kiln, other industrial machines), service, maintenance equipment (incinerator, elevator).
16	Other Heat	Includes all other fires caused by heat from fuel-powered objects, heat from electrical equipment arcing or overloaded, and heat from hot objects not covered by above groups.
17	Unknown	Cause of fire undetermined or not reported.

¹ "Cause" as used here is a shorthand notation for what is sometimes a complex chain of events leading to a fire.

² Note that incendiary fires involving flammable liquids are covered in category 3, not 13.

END
