## SUMMARY

### Research Hypothesis

The hypothesis has been made that external factors of a socio-economic type are correlated with reported crime and calls for police services and can be useful as "predictors". While considerable research has been undertaken to test this hypothesis, the lack of current socio-economic data as well as the size of the unit of aggregation of these data has reduced the value of the research results. Thus, the use of 1960 data as a "predictor" for 1969 criminal and police activities is certainly fraught with considerable difficulty. In addition, correlations using relatively large geographical units such as census tracts have limited usefulness from the point of view of the police administrator. The common sense relationship between what police "do" and the physical, sociological, and economic characteristics of the geographical area in which they "do what they do" is a justification for experimental work when new statistical data become available on a current basis. Such was the situation when the Bureau of the Census conducted a full-scale Census Pretest in the City of New Haven in April 1967.

**Preceding page blank**

### New Haven Census

When the Bureau of the Census announced plans for a census in the City of New Haven as a full-scale test of the proposed procedures for the 1970 census, the opportunity to relate up-to-date measurements with police data arose. In addition, the Bureau of the Census plans included two major innovations. These were the development of an address coding guide as an essential prerequisite for the use of a mail procedure for gathering census data. The second innovation was the plan to tabulate certain data on a block face basis. From the point of view of police administrators, the first innovation gave promise of developing a computerized look-up procedure to relate street addresses to block faces, nearest intersecting street, and tract. This would have significance for police operations in the dispatching of patrol cars and later in the analysis of the characteristics of calls for service. The innovative plan to release selected census data on a block face basis provided an opportunity to substantially improve the usefulness of data analysis over previous censuses where the smallest unit of tabulation was the block. Thus it has long been recognized that a block total for selected characteristics may not be relevant to police operations since police problems may be a consequence of the characteristics of one side only of the block. The expectation, on the basis of the Bureau of the Census' announced plans, that block face data would be available made this aspect of the New Haven Pretest particularly interesting. From a broader point of view, since the New Haven operation was to be a test of the 1970 census procedures, close involvement with the Bureau of the Census operations would serve to provide useful guidance to the law enforcement profession in terms of what problems and data output they might expect on a nationwide basis in 1970.

### New Haven Police Data

While waiting for the delivery of data from the Bureau of the Census the staff of this project assisted in the development of a Central Complaint Desk for the New Haven Police Department. Until the establishment of centralized procedures no useful complaint data were available within the Department. The research support from this project permitted experimental work in defining characteristics of police complaints and responses to the complaints. In addition, experimental work was done with arrest information generated through the operation of the Circuit Court System in the State of Connecticut. Unfortunately, there has been no possibility of matching complaint data with arrest data, but recommendations to make this possible have been made through the project and are in the process of implementation. Unsuccessful efforts were made to develop experimental matching procedures to relate arrest data on individuals to census data on the same individuals. While having due regard to the confidentiality of both types of data, it would appear useful to experiment in 1970 with a matching effort. Through these techniques a great deal of new information could be generated in respect to the socio-economic characteristics of arrested persons. As an aspect of the implementation of Central Complaint procedures in the New Haven Police Department a computer program, LOOKUPAD, designed to permit a computerized identification of block size and nearest intersecting street for addresses of complaints, was written and tested. Input of addresses to the system, an essentially clerical procedure, was not completed nor does the New Haven Police Department currently have its own computer capability.

### Census Data Output

While the field work, essentially a mail procedure, for the New Haven census was completed in April 1967, the special tabulations contracted for by this project were not delivered until late in 1968. In addition, for a combination of technical and administrative reasons, the Bureau of the Census did not deliver any block face tabulations and thereby rendered abortive one of the primary thrusts of this research project. These developments do not, however, suggest the lack of relevance of the research effort. The close working relationship between the New Haven Police Department and the Census Use Office in New Haven has resulted in a useful interchange from which a more realistic appreciation of the Bureau of the Census' procedures and policies has emerged. The special tabulations for the so-called 100% and 25% data are summarized in this report and provide a meaningful description of the City of New Haven on a tract and block basis. These data are not available from any other source.

### Potentials for 1970

Two major results were achieved through this research project. In the first place, the staff of this project together with the leadership of the New Haven Police Department, were able to substantially up-grade Department procedures and to be helpful in implementing plans looking toward computerization of many Department operations. In the second place, continued working relationships with the professional staff of the Bureau of the Census has resulted in a better understanding on their part of the potential contribution which census data may make to police administration. At the same time, the

technical and administrative difficulties which have interfered with the anticipated delivery of census data have been identified. It is felt that a reading of this report will assist police administrators in working more effectively and realistically with the Bureau of the Census personnel after the 1970 census is completed. Unfortunately, there is presently no policy to release block face data from the 1970 census except on a special tabulation basis. Experience with the latter type of procedure was not encouraging in the New Haven test census. However, the plan to develop address coding guides as a part of the 1970 census procedure may well provide a useful tool to many police departments. The overall result of this research project would tend to confirm the view of many police administrators that "internal data" dealing with arrests and complaints and more intensive utilization of this type of data represent the major area to which resources should be committed. Census-type data, when available, should be fully exploited, but the severe limitations on its usefulness will probably not be lessened if present Bureau of the Census policies hold through the 1970 census.

PART I

## CHAPTER I

### THE NEW HAVEN CENSUS PRETEST OF 1967 AS A RESOURCE FOR POLICE ADMINISTRATION

#### Role of Census Data

Article I, Section 2, of the Constitution of the United States, adopted in 1787, provides that an enumeration of the population of the United States shall be made every ten years. Since the first census was taken in 1790 there has been a continuous series of increasingly complex census enumerations which have provided the fundamental information in respect to the socio-economic dimensions of the country. There have been relatively few systematic efforts to relate census-type data to the needs of police administration. In part, this has resulted from the comparative lack of sophistication on the part of personnel of police agencies but, to a larger degree, it has resulted from the practical difficulties presented by census-type data in relation to the unusual statistical materials collected by police agencies. While the Constitutional mandate under which the census is taken every ten years provides for a simple head count, increasing needs for quantitative information about our society has led the decennial census to add questions on detailed population characteristics: education, income, housing, employment, and related aspects of human activity. In fact, the proliferation of decennial census questions has become an acute political issue now being debated in connection with plans for the 1970 census.

**Preceding page blank**

The current debate is one aspect of the increasing sensitivity to "the invasion of privacy". While market research and commercial interests have been actively pressing for the types of data useful to them in their operations, the law enforcement community has not been involved in the development of decennial census programs. Only recently (1968), has the Bureau of the Census organized an advisory panel representing the spectrum of interests in the criminal justice field.

The report of the President's Commission on Law Enforcement and Administration of Justice, "The Challenge of Crime in a Free Society", commented on the apparent rise in crime, particularly in the cities.

"Burglary, robbery, and serious assaults occur in areas characterized by low income, physical deterioration, dependency, racial and ethnic concentrations, broken homes, working mothers, low levels of education and vocational skill, high unemployment, high proportions of single males, overcrowded and substandard housing, high rates of tuberculosis and infant mortality, low rates of home ownership or single family dwellings, mixed land use, and high population density."

In the annual report published by the Federal Bureau of Investigation, "Crime in the United States, Uniform Crime Reports", a list of factors that must be taken into account in interpreting changes in crime rates and in the amount and type of crime that occurs from place to place includes a number of socio-economic variables. These include density and size of population, age, sex, and race composition and economic status of the population.

From the point of view of police administration, the less "aggregate" census-type data are, the more useful they become. Thus, population characteristics summarized for an entire county or urban area are not useful except as a most general guide.

Traditionally, census-type data have been released on a county basis. Beginning in 1940, certain types of data have been published for "census tracts" on a limited basis. (Census tracts are small homogeneous groups of city blocks with a population between 3,000 and 6,000.) By the 1960 census nearly every city with a population of 50,000 or more was divided into tracts. With the availability of tract data a number of police agencies as well as municipal agencies in general, moved in the direction of using tract boundaries as administrative unit boundaries so that data generated by various city agencies would relate to standard geographic units. However, for a complex of reasons, only a few cities have been able to achieve the desirable objective of common geographic definitions for all agency statistics. The availability of tract data made possible a more meaningful analysis of socio-economic characteristics in relation to crime records maintained by local police departments. One significant use of census tract data for this purpose, using tract information from the census of 1950, was that by Dr. Calvin F. Schmid in his articles on urban crime areas in the City of Seattle. More recently, under a grant from the Office of Law Enforcement Assistance, the Franklin Institute in cooperation with the Philadelphia Police Department has made use of census tract data to develop a technique for predicting crime occurrences, "Computer-Aided Crime Prediction in a Metropolitan Area."

## New Haven Census Pretest of 1967

Statistical data generated through the decennial census are referred to as small area data when they are available for tracts and blocks. Because of the increasing interest in small area data by commercial users as well as public agencies, the Bureau of the Census established a Census Advisory Committee on Small Area Data in 1965 for the purpose of giving guidance on producing improved and more flexible small area data from the 1970 census. As a result of a recommendation from this Committee, the New Haven Census Use Study was created. In planning for the 1970 census it was recognized that traditional methods of enumeration by using field interviewers would encounter significant difficulties because of labor shortages and rising costs. As a consequence, the administration of the Bureau of the Census began to formulate plans for the use of mail-out, mail-back procedures and the continued use of sampling procedures for certain census respondents. Several full-scale field tests were scheduled in the 1970 census planning procedures. The New Haven, Connecticut, Standard Metropolitan Statistical Area (S.M.S.A.) was selected as a location for a census pretest. Because of the significant leadership of Mayor Richard C. Lee and his administration in the area of federal/state and city urban programs as well as the influence of Yale University, New Haven was a logical test site. A Census Pretest Office opened in February 1967, in New Haven and the complete census field operation was over by June. In order to supplement the field experience with a study in depth of "user needs" the Bureau of the Census opened a Census Use Office in the City of New Haven and this office, until its closing on June 30, 1969, has provided special tabulations, experimented with new methods and generally sought to work cooperatively with any group seeking to use 1967 census data. Mr. Coby C. Smith was director of the office and has served as liaison officer with this O.L.E.A. project and the Bureau of the Census.

### Origin of the Office of Law Enforcement Assistance Project

A working relationship was established between the Census Use Office and Chief Francis V. McManus of the New Haven Police Department in November 1966. The Police Department identified its interest in obtaining data tabulations from the Census Pretest of April 1967, for tracts and blocks. However, the most important aspect of the announced plans was the expectation that certain data would be made available on a "block face" basis. ("Block face" is a term which refers to the side of a block.) In general, a block has four sides and the total count of the particular population characteristics for the block is the smallest unit for which census data have traditionally been released. A police administrator finds that, from a policing point of view, a block has significantly different characteristics on each of its faces. Thus, one face of a block may have commercial occupancies such as bars and grills which generate police activities while the other three sides may have residential occupancies calling for different kinds of police services. As a consequence, the Census Bureau plans to use block faces as "building blocks" to provide census data for various local administrative areas were immediately relevant to police administration and, if effectively implemented, would greatly stimulate the use of census-type data in police applications. As a consequence, Chief Francis V. McManus wrote to the Census Use Office in November 1966, and said, "The possibility of correlating criminal and Motor Vehicle data already maintained in machine processable form, with socio-economic data from small areas such as block face, offers tremendous potential to a forward-looking police department for purposes of planning, crime prevention, advantageous deployment of personnel, etc."

The New Haven Police Department formulated a project proposal for support from the Office of Law Enforcement Assistance of the U.S. Department of Justice. This was the genesis of O.L.E.A. Grant #171.

#### Census Pretest Procedures

In order to use a mail-out, mail-back procedure it was necessary for the Bureau of the Census to develop a list of all dwelling unit addresses within the City of New Haven. This was accomplished on the basis of the purchase of a commercially available list of addresses which was then verified and supplemented by using employees of the Post Office. Thus, each delivery carrier verified the commercial list of addresses by checking against his route list. Using this technique, with modifications appropriate for areas not included in the City delivery zone, it was hoped that subsequently all dwelling units were identified by means of an address. No information as to the accuracy of the address listing has been made available by the Bureau of the Census. Subsequent to the preparation of lists of addresses an envelope was mailed to each dwelling unit which normally receives mail. The envelope contained the census form and instructions to fill out the form and to mail it back to the Bureau of the Census on April 5, 1967. Follow-up procedures were used in cases where census forms were not returned. However, no information on the completeness of the response has been made available by the Bureau of the Census in respect to either the initial mailing or the field follow-up. In any case, all tabulations released by the Bureau of the Census were based on the procedures which have just been outlined and although the Bureau of the Census, for its own internal purposes, must have a judgment in respect to under-enumeration no data on this crucial question have been made available to the staff of this project.

Since it is reasonable to assume that under-enumeration is likely to be a particularly troublesome problem in both ghetto and high income areas, the impact of under-enumeration, in respect to certain socio-economic characteristics of the population such as race and income, may be substantial. Any attempt to utilize small area data under these circumstances could involve a considerable margin of error. It has been a disappointment that the Bureau of the Census has provided no guidance in respect to this problem. Since the Census Use Office has worked only with the tabulations and has not been in a position to report the experience of the original Census Pretest field staff, it is not possible to reach any useful conclusion in respect to the estimate of under-enumeration.

Consistent with the policies of the Bureau of the Census implemented in the 1960 census, all identifiable dwellings received one of two types of questionnaire, the short form or the long form. The short form included nine questions in respect to the characteristics of people in the household and eleven questions related to housing characteristics. The long form which was sent to 25% of the households selected systematically, not randomly, consisted of a 20-page questionnaire which, in addition to all of the questions included in the short form, asked for additional information on education, employment, earnings and the like. On page 8 a part of the short form is shown with typical responses. The census forms are so designed as to be "read in" to an electronic calculator with the use of FOSDIC (Film Optical Sensing Device for Input to Computers). The Census Pretest was conducted for the entire New Haven Standard Metropolitan Statistical Area (S.M.S.A.) which, as shown by the map on page 9 embraces a number of towns in addition to the City of New Haven.

# Steps in Filling Out Your Census Form

U.S. DEPARTMENT OF COMMERCE  
BUREAU OF THE CENSUS

FORM DX-4  
(1-27-67)

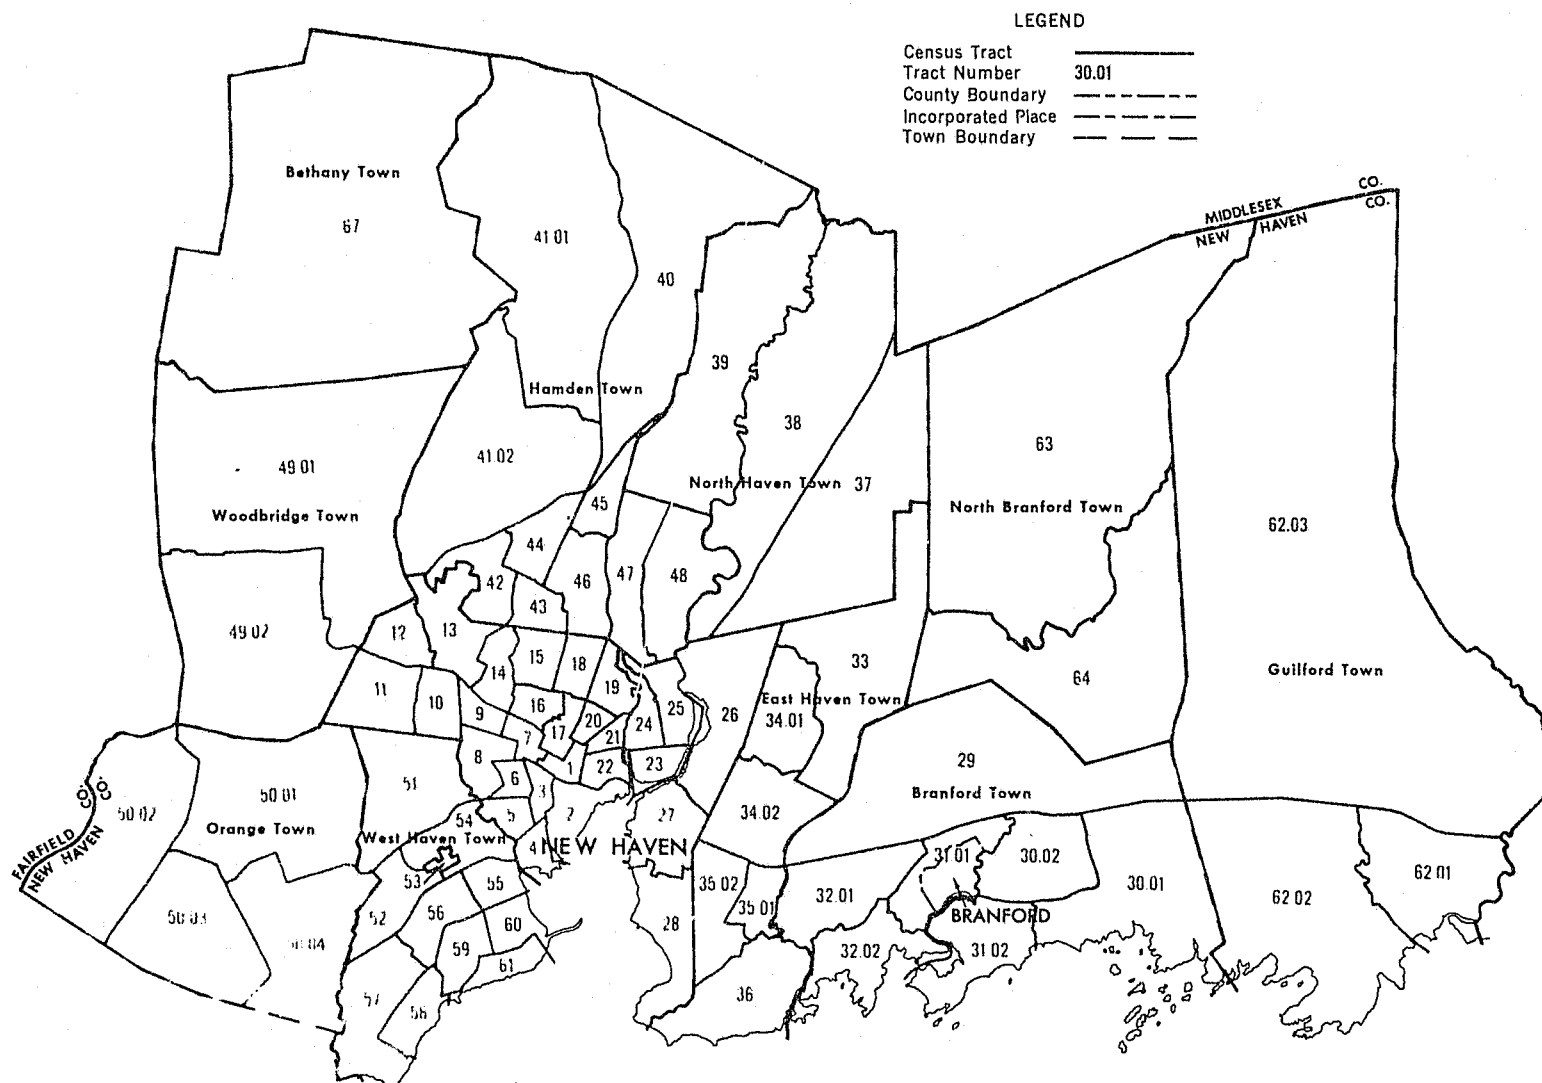

- Look at the example below to see how written entries and circle fill-ins are made.
- Answer Question A on page 1 of the Census form.
- Fill page 2 of the form; note the instructions overprinted on the example below.
- Answer Questions 11 and 12 on page 3 of the form.
- Answer Questions H1 to H31 about your home or apartment on pages 3, 4, and 5 of the form. Helpful instructions are given on the back page of this sheet.
- Then, starting with pages 6 and 7, fill the specified set of facing pages for each person listed on page 2 of the form. Helpful instructions are given on the reverse side of this sheet.
- Answer Question B on page 20 of the form.
- Check out and mail your form, as explained on page 20. Mail the form on Wednesday, April 5, or as soon thereafter as possible.

Line No.	Col. 1 NAME AND SOCIAL SECURITY NUMBER of each person who was living here on Wednesday, April 5, 1967 or who was staying or visiting here and had no other home.  Write name in this order: Head of the household Wife of head Unmarried children, oldest first Married children and their families Other relatives of the head Persons not related to the head	RELATIONSHIP TO HEAD OF THIS HOUSEHOLD		Col. 4 SEX  Fill one circle	Col. 5 COLOR OR RACE  Fill only one circle (If "Other," also write in race)	DATE OF BIRTH			Col. 9 MARITAL STATUS  Fill one circle
		Col. 2 Exact relationship Write relationship of person to head of the household. For example: Head      Mother-in-law Wife      Lodger's wife Son      Maid Grandson      Partner	Col. 3 Relationship category  Fill one circle			Col. 6 Month and year of birth and age last birthday  Write	Col. 7 Month of birth  Fill one circle	Col. 8 Entry for year of birth  Fill one circle for decade      Fill one circle for exact year

# CENSUS TRACTS

## NEW HAVEN, CONN., STANDARD METROPOLITAN STATISTICAL AREA

## CHAPTER II

### STATISTICAL PROFILE OF THE CITY OF NEW HAVEN 1960-1971

#### Result of the Pretest

In general, the results of the Census Pretest of April 1967, showed population changes in the New Haven Standard Metropolitan Statistical Area (S.M.S.A.) and in the City of New Haven similar to those being experienced in other major metropolitan areas of the United States. Thus, while the total population of the Standard Metropolitan Statistical Area increased 8.2% from April 1, 1960, to April 5, 1967, the population of the City of New Haven declined by 6.8%. The white population of the S.M.S.A. rose by 4.3% but declined by 16.4% in the City of New Haven. At the same time, the non-white population of the S.M.S.A. rose 54.6% and in the City of New Haven by 48.4%. The total non-white population in the S.M.S.A. was 38,251 practically all of which, amounting to 33,636, was resident in the City of New Haven. Although the immediate reaction to the release of these figures by the Bureau of the Census was an expression of disbelief in terms of the decline of population in the central city, there is no reason to believe that the aggregate figures are inconsistent with known patterns in urban centers since 1960.

Since this report is concerned solely with the City of New Haven no data for the entire S.M.S.A. will be shown in detail. The following data summarize the changes in total population for the components of the S.M.S.A.

Population of the New Haven, Connecticut

Standard Metropolitan Statistical Area

Area	April 5, 1967	April 1, 1960	Increase, April 1, 1960 to April 5, 1967 (percent)
The SMSA	347,094	320,836	8.2
Bethany town	3,118	2,384	30.8
Branford town, total	19,210	16,610	15.7
Branford borough	2,281	2,371	- 3.8
East Haven	24,354	21,388	13.9
Guilford town	10,500	7,913	32.7
Hamden town	47,052	41,056	14.6
New Haven city	141,752	152,048	- 6.8
North Branford town	10,250	6,771	51.4
North Haven town	21,406	15,935	34.3
Orange town	12,791	8,547	49.7
West Haven town	49,958	43,002	16.2
Woodbridge town	6,703	5,182	29.4

Census Data by Tract

Major changes in the period 1960-1967 in the population characteristics of the City of New Haven with particular reference to the characteristics which are relevant to police administration will now be examined. These data are presented on a tract basis. Block statistics as well as special tabulations by traffic zone are shown in Appendix C. The data by tract in respect to age, race, and sex were published in "Current Population Reports, Special Censuses", Series P-28, No. 1459, December 1, 1967. This report is the only publication issued by the Bureau of the Census of the

results of the special census of the New Haven S.M.S.A. All other data were released either in preliminary format or in the form of special tabulations prepared on a cost basis for this report.

The tabulation on page 13 shows total population and non-white population by tract for 1960 and 1967. Of the 28 tracts the total population declined in 21 and increased in 7. The non-white population increased in 23 tracts and declined in 5. Tracts with a major concentration of non-white population include tracts 3, 5, 6, 7, 8, 12, 13, 15, 16, 18, 21. In general, the tracts with a significant percentage of non-white population in 1960 increased in non-white population in 1967. The table on page 14 summarizes three major socio-economic variables for 1960 and 1967 by tract. These are: average rent, percent non-white and percent overcrowded.

A familiar statistical device is used to show the relationship between the percent non-white population by tract in 1960 and 1967. The scatter diagram on page 15 shows the 1960-1967 relationship. A linear line of relationship (called a least squares line of regression) has been mathematically fitted and is plotted on the scatter diagram. In addition, a coefficient of determination ( $r^2$ ) was calculated with a value of 80.62% indicating a rather close relationship between the 1960 and 1967 values. The standard error of estimate ( $S_{y,x}$ ) which measures the amount of "scatter" around the line of regression is 9.24%. (A discussion of these statistical procedures may be found in any general textbook as, for example, John I. Griffin's "Statistical Methods and Applications", New York, Holt, Rinehart and Winston, 1962.)

Certain additional socio-economic characteristics have been measured for the 28 tracts in the City of New Haven. The table on pages 16 and 17 shows total

population, Negro (this excludes non-Negro, non-white), female, and selected age groupings. The table also includes an index of family instability which was calculated from census data by relating the number of persons divorced and separated to the total number reported as married. In general, a high index of family instability is correlated with a high percentage of non-white population in the tract, this is a familiar phenomenon in major urban centers. (For technical reasons the data in Tract 1 did not represent a complete tabulation of characteristics.) In addition, percent figures are shown for one person households, for households with six or more persons, and for families with female head. Certain housing characteristics are indicated including percent of one unit structure, percent owner occupied, average monthly rental and average value of owner occupied structure. Clearly, these characteristics by tract are closely inter-correlated. Lastly, a percent figure is shown for each tract for the number of persons in crowded household units. The Bureau of the Census defines an overcrowded unit as one with 1.01 or more persons per room.

For example, the relationships between these variables may be seen if a comparison is made between two significantly different tracts in terms of socio-economic characteristics.

Tract	% Negro	Index of Family Instability	% Owner Occupied	Average Monthly Rental	% in Crowded Household Units
16	75.6%	26.4%	16.2%	\$ 78	31.5%
28	0.0%	3.6	77.2%	\$ 106	9.2%

If a comparison is made between the percent of overcrowded household units by tract in 1960 with 1967, the scatter diagram shown on page 20 results. Again, a mathematically fitted line is shown. The coefficient of determination is 71.33% indicating a close relationship between the two sets of observations. The standard error of estimate is 9.60%. If a similar analysis is undertaken in terms of average monthly rental, the scatter diagram on page 21 results. Again, the low average rental tracts in 1960 are, in general, the low average rental tracts in 1967. Again, a line of relationship has been fitted. In this case, the coefficient of determination is 75.25% and the standard error of estimate is 9.08%.

#### Other Socio-Economic Measures

Certain additional measures of socio-economic characteristics of the population of the City of New Haven can be developed from census data. The table on page 22 shows the number and percent of persons completing 12th grade education and above by tract in 1967. This table is based on a special tabulation made from the 25% data. Due to difficulties with the computer program, it was not possible to break out the number of persons with less than elementary school education and those completing only part of their high school education.

One of the most interesting economic variables is family income. In the absence of family income data it is common to use related measurements such as average rental, value of owner occupied home, and car ownership. In the census of 1960, the 25% sample of respondents were asked to provide information on family income for the year 1969. The table on page 23 shows the distribution of families by income, by tract. Again, a group relationship to the previously examined socio-

economic variations is evident. The range of median family income by tract in 1959 was from a low of \$3,848 in tract 16 to \$10,804 in tract 11. Unfortunately, the Bureau of the Census did not generate a distribution of income by tract from the Census Pretest of 1967. The only income information available is a distribution for individuals for the entire city.

	<u>140,897</u>

Historically, the large urban centers of the United States have been the homes of substantial numbers of persons born in foreign countries. With the passage of time and the continued restriction on foreign immigration, the "foreign born" population has become less significant. The table on page 25 shows that in 1967 the highest percent of persons born in a foreign country was in Tract 6 and this amounted to only 6.8%. However, a new form of in-migration has become significant, that is, immigration into urban centers from other parts of the United States. Characteristically, a considerable percent of Americans move from one State to another and since World War II movement from the South, particularly of Negroes, has been important. No distribution by race in terms of persons born in another State was generated for the 1967 census. However, the table on page 26 shows the number of persons born in another State grouped in terms of New England and Mid-Atlantic, South, and All Others. It will be noted that the percent of persons born in another State by tract is relatively low

for most tracts but that the percent of persons born in the South by tracts is high for many tracts. It is reasonable to assume that most of the persons born in the South who were living in New Haven in 1967 were Negro. To test this hypothesis the percent of persons born in the South by tract was correlated with the percent non-white in the same tracts. The scatter diagram on page 28 shows the relationship. The co-efficient of determination was 77.01% and the standard error of estimate 10.06%. This analysis is an illustration of the type of relationships which can be developed from census-type data.

## CHAPTER III

### RECORD PROCEDURES IN THE NEW HAVEN POLICE DEPARTMENT

#### The New Haven Police Department

At the time of the initiation of this O.L.E.A. project the New Haven Police Department operated with two precincts. Precinct No. 1 had about 140 patrolmen assigned to it and Precinct No. 2 about 100 patrolmen. The Department's strength consisted of a chief of police, 4 chief inspectors, 2 deputy chief inspectors, 10 captains, 13 lieutenants, 23 sergeants, 37 detectives, 276 patrolmen and miscellaneous personnel to a total number in the Department of 461. In 1967, there was no distinct unit specifically assigned to the records and statistical function.

Records were kept of activities in three major areas: complaint activity, arrest activity, and motor vehicle accident data. Since the purpose of this research project was to relate census-type data to police department data, it is essential to describe the types of data available in the New Haven Police Department. A considerable portion of the project resources were expended within the Police Department in an effort to assist that Department in gathering and maintaining more useful records. Circumstances impacting upon the police situation in the City of New Haven also led to a reinforced effort to improve record keeping and there can be no doubt that the present substantially improved records situation was, in part at least, a consequence of the support available from this project.

In 1967, and for many years prior thereto, the source document for complaints handled by the Patrol Division of the Department was the Patrolman's Station Report. In this report the officer summarized his activity in handling complaint assignments. These reports were transcribed by hand into a large daily log called the Complaint Book. There were two such logs, one kept in each precinct. In addition, the Plainclothes Divisions which included the Detective Division, the Gambling and Narcotics Division, and the Youth Division, recorded details of complaints on lettersize complaint forms. Such information was kept in the Plainclothes Divisions. Under this system there was no central records procedure nor were any of the data in machine processable format. There was universal agreement within the Department that the procedures required a fundamental overhaul, but resources to accomplish this were not available.

The second category of police data related to arrest activity. Such information was gathered by the two precincts' Traffic and Plainclothes Divisions. Arrest information was transmitted by telephone to a recording officer who entered it on a Master Daily Arrest Sheet. In addition, as required by the State of Connecticut, arrest information was recorded on a Circuit Court Uniform Arrest Report (Chapter IV discusses Court record information). The third type of police data related to motor vehicle accidents in respect to which all Connecticut police agencies used a standard form designated, Police Report of Motor Vehicle Traffic Accident. Information from these reports was retained in the Traffic Division.

### Impact of the New Haven Disturbances

While the information on complaints and arrests was provided in the required form to the Federal Bureau of Investigation for their Uniform Crime Reports, there was essentially no effective use for analytical or manpower allocation purposes of police data within the New Haven Department. At one point, presumably about the year 1946, annual arrest data back to 1861 were graphed and the analyst commented in the following intriguing manner.

"The results show declines in other assault, larceny, and burglary; a steady rate for murder, aggravated assault, and manslaughter; and increases for forcible rape and robbery. The declines in other assaults and larcenies were attributed to changes in arresting policies over the years. The increases in forcible rape and robbery were regarded as results of the diffusion of the auto, and the constant levels of murder, aggravated assault, and manslaughter and the decline in burglary were interpreted as evidence for the gradual urbanization, stabilization, and enrichment of the New Haven population. Also the business cycle was associated with every crime except forcible rape, other assault, and larceny. Crimes against person seemed to show a positive relationship with the business cycle, whereas crimes against property exhibited a negative relationship. Wars did not have a strong influence on any of the crimes examined, although it was weakly associated with larcenies."

In late August 1967, the City of New Haven was rocked by several days of major rioting. The impact was perhaps greater psychologically on the City's leadership than the actual damage done during the disturbances. Mayor Richard C. Lee has been a leader among urban mayors and the extent to which the urban blight in the old city had been ameliorated through massive urban renewal projects made the city notable. In addition, Mayor Lee's vigorous community action programs, particularly through Community Progress, Inc., were regarded nationally as a classic example of an effective anti-poverty program.

On an experimental basis, staff of the O.L.E.A. project transcribed the handwritten information for April 1967, from the two precincts' Complaint Books and machine processed these data in order to generate distributions of complaints by type, hour of day, and other characteristics. With the introduction of a Central Complaint Desk the precinct Complaint Books were discontinued. Following the activation of the Central Complaint Desk the staff of the O.L.E.A. project machine processed information from the CCB-1 forms for the months of August, September, and October 1967. These tabulations for the categories listed above were provided to the Chief and represent the first measurements available in New Haven for such aspects of police activity as response time, activity by squad car, and the like. From this initial effort the New Haven Police Department has refined and expanded the analyses of Central Complaint Desk information and is now exploring the appropriate type of computer capability to be installed in the Department. Currently, an IBM 360 in the Controller's Office has been used together with an IBM 1401 available to the O.L.E.A. project director in New York City.

#### Selected Tabulations from CCB-1 Forms

As the Central Complaint Desk procedures were refined, and as the training of Complaint Desk personnel proceeded under the officer in charge, Lt. James Shelly, the quality of information improved. Automatic timed stamping was introduced and continuous recording equipment installed to permit subsequent verification of reports. While considerable interest attached to the tabulation of complaints by race it is clear that this category depends upon the judgment of the complaint writer and therefore contains considerable margin for error. Insofar as the information by ethnic group is valid, it threw light upon several aspects of the New Haven environment.

It is sufficient for the purposes of this report, which in no way is concerned with the causes of the disturbances, to point out that there was a sudden realization of the inadequacies of police data, and by the same token, the inadequacies of small area economic and social data. During the disturbances approximately 580 persons were arrested and a confidential analysis of the socio-economic characteristics of the arrested persons was prepared. Of the persons arrested 382 were classified as Negro males, 14 Negro females, 53 Puerto Rican males, 124 white males and 7 white females. (Major responsibility for this analysis rests with Dr. John J. Herder, then special assistant to the Mayor and the then Lieutenant James F. Ahern.) With the implementation of Central Complaint Desk procedures the analytical situation underwent substantial improvement. For example, early in 1948, a comparison of ten days in March with ten days in April, in terms of number of complaints, was undertaken for the Chief of the Department in order to test significant differences between the two periods, one of which was characterized by disturbances. The tables on pages 34 and 35 were generated by the staff of this project and permitted a judgment of no significant differences between the weekday disturbances and the weekend disturbances for the two months under study.

#### Development of the Central Complaint Desk

A Central Complaint Desk is an essential first step in providing useful and reasonably complete information for police management purposes. Even before the disturbances impacted, plans had been developed for a Central Complaint Desk procedure and steps were underway to install the necessary communications equipment and to train personnel to man the desk. The consequence of introducing the Central

Complaint Desk was to eliminate record keeping by the precincts. (The New Haven Department has since consolidated its two precincts.) A Central Complaint Desk form (CCB-1 form shown on page 37 ) was designed for key-punching. The punchcard format used is shown on page 38 . Tables of the following types may be prepared from such information.

---

I. Daily

- A. Average Response Time
  - 1. Total
  - 2. By Major Category
- B. Lowest and Highest Response Times
  - 1. For All Complaints
  - 2. By Major Category
- C. Total Number of Complaints
  - 1. By Major Categories

ENERGY PURPOSE 20 FIELD

For example, in October 1967, a total of 6,783 complaints were recorded, of these 1,237 had no ethnic coding. Of the remainder, 4,341 were classified as white, 1,139 as Negro and 66 as Puerto Rican and All Others. The average response time to complaints classified by ethnic group indicated: white 4.7 minutes, Negro 6.3 minutes and Puerto Rican and All Others 4.9 minutes. In general, however, the disturbances by race in terms of location of complaint, appear to be consistent with the population characteristics of the area. Subsequent to the completion of action in the field by the assigned squad car, the information on the CCB-1 form is checked against the patrolman's field report.

The following are four tables prepared by the staff of the O.L.E.A. project which indicate the kinds of information which are available for the first time to police commanders in New Haven.

## CHAPTER IV

### COURT RECORDS FOR NEW HAVEN ARRESTS

#### Circuit Court Data

The Circuit Courts of the State of Connecticut maintain a Central Accounting Unit at Middletown, Connecticut where the records of court activity are machine processed. At the present time, unit record equipment is in use rather than EDP processing. Interest in the Circuit Court procedures arises from the possibility of relating Circuit Court information to New Haven Police Department records. For this reason court records have been investigated in connection with this research project.

The basic source document for the Circuit Court Central Accounting procedures is the Uniform Arrest Report (CCT38). The Uniform Arrest Report is filled out by the arresting officer at the time of arrest. It provides name of the accused, home address, sex, color, date and place of birth as well as department case number, description of charges and information on action taken by the court. Copy of this form appears on the following page.

UNIFORM ARREST REPORT No. B252226

FORM CCT 38 REV. 10-66

While the Circuit Court data provide an invaluable source of analytical information in respect to arrested persons and the disposition of their cases, it was not possible to relate the court records to the New Haven Police Department complaint records. The absence of a common identifier in the punch cards produced by the Circuit Court Central Accounting Unit made a match impossible. The absence of such a common identifier is explained by the historical fact that no police department in Connecticut had attempted machine processed matching of police and court records. As a result of the experimental work done in this research project the recommendation was made by the New Haven Police Department that the police department complaint record number be added to the court record punch card. When this recommendation is implemented it will be possible to trace arrested persons from the moment of arrest through final disposition of their cases by the Circuit Court.

#### Matching Experiment

A matching experiment was undertaken early in 1968, to attempt to match court records manually in two directions on individually arrested persons. One attempt was made between the court records and arrest records and the other was between court records and individual schedules obtained during the Census Pre-Test of 1967.

In structuring the matching experiment a random sample was drawn from a listing of Circuit Court arrest records for the 6th Circuit Court which is located in the City of New Haven. This random sample provided the docket number for each arrested person's case. The docket was then examined at the Circuit Court and certain identifying information was obtained about the arrested persons. The table on the following page identifies the information obtainable from the docket.

### Matching Experiment

The project staff provided the Census Use Office 136 records from the Circuit Court data. The following was the outcome of the matching experiment.

	Town	Block Face Area Match	Household Match	Person Match Age, Race, Sex	Person * Match Age, Race, Sex, <u>Name</u>
Significant Matching Percentage For Police Study	100%	70%	60%	50%	80%

\* By hand using microfilm

Several matching experiments were conducted by the Census Use Office including area matching address matching, and individual matching. In the case of the arrest data, the block face area match produced 70% matches while the person match, using age, race, sex, and name achieved 80%, but required hand procedures using microfilm of the census schedules. Matching by Social Security Number is not relevant to census work since the number will not appear on the 1970 census questionnaire. This is a concession to the critics of the "invasion of privacy" issue.

It is evident that considerable information can be developed from the docket which is not available from the Circuit Court punch cards which do not provide name, race, or place of birth. The Circuit Court detail cards are in the following format.

Circuit Court Detail Cards

<u>Fields</u>	<u>Contents</u>
1-4	Month and Day of Court
3	Jury Codes
	1 Jury of Six
	2 Jury of Twelve
6-8	Alcoholic )
	Narcotic ) Involved in the offense
	Sexual Deviate )
9-10	Year of Birth
11	Sex
	1 Male
	2 Female
12-16	Statute
	Connecticut General Statutes except 53-000 code for any town ordinance.
17	Plea Code
	Guilty 1
	Not Guilty 2
	Nolo 3
18	Judgement Code
	Guilty 1
	Not Guilty 2
	Bond Forfeiture 3
	Nolled 4
	Bind Over Superior Court 5
	Dismissed 6
	Trans. to Juvenile Court 7
	Judgement Suspended 8
19-21	Jail Term 30 d - 30 days
	3 m - 3 months
22-25	Fine Dollar amount
x in 25	Violation Bureau Payment
26-29	Remitted Amount of fine
	Remitted by Judge
30	Imprisonment Jailed in lieu of fine
31	Appeal If the case is appealed this column is punched
32-34	Bondsman's No.

<u>Fields</u>	<u>Contents</u>
35-38	Amount of Bond x in 38 No Bail Compact
39-41	Officer's Shield No.
42	Police Department 1 - State Police 2 - Local 3 - All others (i.e.: Game Wardens, Dog Wardens, Water Districts, etc.)
43-44	Type of Case MV - Motor Vehicle CR - Criminal
45-46	Circuit No.
47-51	Docket No. x 51 revised abstract
52-54	Offense Town
55-56	Circuit No.
57-61	Receipt No.
62-63	Month
64-65	Day of Month
66	Type of Case 8 - Motor Vehicle 9 - Criminal
67-68	Transaction Code 51 - Motor Vehicle 52 - Misdemeanor 53 - Felony
69-75	Amount Collected in dollars and cents
76-78	Trial Town
79-80	Blank Columns

A manual search for the sample of approximately 150 cases in the files of the New Haven Police Department presented a number of difficulties in matching. Although the Uniform Arrest Report form is filled out by the arresting officer and a carbon of the snap-out form is retained in the department file, many of the forms are not filled out completely. A more basic problem arises in that certain elements of information on the arrested person are converted or added to after the arrested person moves through the court process. As mentioned above, the adding of the common identifier will obviate these problems in making a match within the police department files.

At the request of the Census Use Office the random sample of arrested persons was turned over for the purpose of conducting a matching experiment with Census Pre-Test schedules. The Bureau of the Census is interested in matching experiments in order to gain a feeling in respect to completeness and accuracy of the original enumerative effort. Analagous matching experiments have been conducted in respect to school records, hospital patient information and other lists of individuals. Because of the confidentiality regulations under which only sworn employees of the Bureau of the Census may examine individual schedules, no results of specific matches are reported. In this particular experiment the Census Use Office in New Haven undertook a manual match reading microfilms of the individual schedules. A computer match was also attempted. Due to a combination of technical difficulties no useful results from this matching experiment were reported from the Census Use Office.

#### Court Record Tabulations

The punch cards from the Circuit Court Central Accounting Unit were used to prepare a number of experimental listings. When a common identifier is added to the punchcard, listings can be related to New Haven Police Department arrest data. However, as indicated in Chapter III, record procedures within the Department still do not permit a match between complaint information from the CCB-1 report form and arrest information. Tabulations made from the Circuit Court data may be used to develop a profile of arrested persons, offenses for which arrested, and disposition in the criminal justice process. Thus, using records of arrested persons handled by the 6th Circuit Court during the months of April, May, and June 1967, showed the following statute code violations to have been most common:

Frequency of State Code Violations

<u>Offense</u>	<u>Frequency</u>
Intoxication	873
Breach of Peace	558
Allowing Person under 16 to operate Motor Vehicle	147
Failure to obey traffic signal light	145
Failure to obey Stop sign	127
Following too closely	108
General larceny	102
Resisting officer	82
Gaming in general	76
All other Offenses	2,274
Total	<u>4,492</u>

A tabulation of arrests by officer's shield number provided interesting information on activities of individual members of the department. Of course, the number of arrests made by individual officers was closely related to the needs of the current assignment. Other possible listings from the court schedules included: Number of Offenses by Category - Alcoholic, Narcotics, Sexual Deviate; Age and Sex of Offenders by Class of Offense; Statute Code by Frequency of Offense; Type of Case, Motor Vehicle or Criminal; Result of Court Action by Offense; Jail Term by Length and Fine by Amount. Tabulations of this type while not directly related to police management problems can, with analysis, throw light on the "quality" of arrests. In addition, data of this type will highlight operational attitudes of the courts.

Consult The President's Commission on Law Enforcement and Administration of Justice, "The Challenge of Crime in a Free Society," p. 8, for a chart reflecting the entire criminal justice system.

The New York State Identification and Intelligence System (NYSIIS), with a powerful computer capability, is developing a data base of over 500,000 criminal history records which will permit an analagous type of analysis of the characteristics<sup>2</sup> of arrested persons.

The Connecticut Circuit Court Data should be utilized in relationship to the New Haven Police Department arrest and complaint files. To accomplish this will require the implementation of the recommendations developed from this project.

## CHAPTER V

### CENSUS PRETEST DATA OUTPUT

#### Output for General Distribution

As has been indicated in Chapter I, the major thrust of the Census Pretest in 1967 in the City of New Haven was to experiment with proposed procedures to be used in the United States Census in 1970. As a by-product of the census effort in New Haven, a Census Use Office was established primarily to investigate ways in which small area data (tract and block data) might be used at the local level. While the Bureau of the Census has tried to preserve uniformity in the geographical boundaries of tracts, changes in cities have made this an unattainable goal. Long-term comparisons from census to census by tract and block are affected by new streets, block combinations and other changes. Appendix C provides a list of the census tract and block equivalents from the census of 1960 and the census pretest of 1967. Publication of statistical data resulting from the census pretest was thus not a major objective of the Bureau of the Census. In Chapter II reference has been made to the only published report to emerge from the pretest effort, that is the report of December 1, 1967, which presented age, race, and sex data on a tract basis.

It has previously been indicated that the Census Use Office worked with the enumerators' reports and tabulations prepared therefrom without the possibility

of further field verification. As a consequence, the series of experimental efforts conducted by the Census Use Office should be regarded essentially as demonstrations of possible manipulations of data rather than having substantive content. For example, a series of narrative format analyses were prepared for each tract, each such analysis consisting of 12 pages. This type of analysis was intended for the general user.

### The Imager Series

Consistent with the pattern of the 1960 census, all persons receiving questionnaires in the 1967 pretest were asked a limited number of questions. The responses to these questions were referred to as the 100% data, that is, 100% of all persons who responded had been asked this group of questions. The 100% data was made available by the Bureau of the Census in the Imager series which consisted of 41 tract tables for the City of New Haven and 25 block tables. The Imager series was delivered in the form of 8-1/2 x 11 size reproductions of computer printouts and were made available to users for purchase. In the original specifications of the data requirements for the O.L.E.A. study, the following tabulation request was specified which, it was felt, would provide the essential socio-economic variables for correlation with police data.

---

#### Tabulation Request Based Upon 100% Data

---

##### I. Population Characteristics

1. Number of Persons
2. Number of heads of households
3. Number of persons, male and number of persons, female
  - a. 0-5 years of age
  - b. 6-15 years of age
  - c. 16-18 years of age
  - d. single age groups: 15-16-17-18
  - e. 19-21
  - f. 22-24
  - g. 25-64
  - h. 65-over

4. Race

- a. Number of persons, White
- b. Number of persons, Negro
- c. Number of persons, Other

5. Household Size (number of households)

- a. 1 person
- b. 2 persons
- c. 3 persons
- d. 4 persons
- e. 5 persons
- f. 6 persons or more

II. Housing Characteristics

1. Number of dwelling units

2. Number of persons per dwelling unit

- a. 1
- b. 2
- c. 3
- d. 4
- e. 5
- f. 6 or more

III. 3. Dwelling unit value:

a. number of dwelling units owned valued at:

- 1. less than \$10,000
- 2. from \$10,000 to \$19,999
- 3. from \$20,000 to \$29,999
- 4. from \$30,000 to \$39,999
- 5. from \$40,000 or over

b. number of dwelling units rented at:

- 1. less than \$60 per month
- 2. from \$60 to \$90 per month
- 3. from \$91 to \$120 per month
- 4. more than \$120 per month

The Imager series provided the substantial bulk of the tabulations requested. However, the unit of tabulation was limited to the tract and block and did not include block face information. Data not available through the Imager series involved special tabulations procedures. Even in the case of the Imager series confidentiality rules, as interpreted by the Bureau of the Census, resulted in some cases in the combination of blocks or in the failure to printout certain data. For example, when fewer than five housing units were contained on a single block, the data for that block was combined with the information for a contiguous block within the tract. Similar confidentiality procedures suppressed certain breakdowns of population characteristics such as the ethnic distribution of population for certain blocks.

#### Special Tabulations

In order to meet the stated objectives of the O.L.E.A. project it was necessary to request special tabulations from the Bureau of the Census. The special tabulations related to two major categories, 100% data sorted in a special way (for example, population by single age groups), data tabulated on a special geographic basis (for example, New Haven Traffic Zones). Special tabulations were prepared on the basis of a "user contract" under which the Bureau of the Census charged the O.L.E.A. project for some of the expenses involved. Due to a combination of technical and administrative factors, the special tabulations were not delivered until late in September 1968. Unless the programming problems encountered in the New Haven experiments are resolved by the Bureau of the Census substantial delays in any special tabulations of the 1970 census can be anticipated.

The Bureau of the Census made no general distribution of tables based upon 25% data. These data were the result of responses to the "long form" questionnaire which was provided to 25% of the respondents. In general, the 25% data relate to additional characteristics of the population such as education, employment, and income. The following was the tabulation requested by this project for 25% data.

---

Tabulation Request Based Upon 25% Data

1. Education
  - a. Number of persons - none
  - b. Number of persons 1-8 years
  - c. Number of persons 9-12 years
  - d. Number completed high school
  - e. Number of persons with 1-4 years of college
  - f. Number of persons completed college
  - g. Number of persons with additional education
2. Employed Persons - Number of employed persons per household category
  - a. Number of families with 1 person working full or parttime
  - b. Number of families with two persons working full or parttime
  - c. Number of families with three persons working full or parttime
  - d. Number of families with four or more persons working full or parttime
3. Type of Employment
  - a. Number of industrial employees
  - b. Number of service employees
  - c. Number of professional employees
4. Number of Unemployed
5. Family Income
  - a. Number of families with income less than \$3,000
  - b. Number of families with income between \$3,000 - \$5,000
  - c. Number of families with income between \$5,001 - \$7,000
  - d. Number of families with income between \$7,001 - \$9,000
  - e. Number of families with income between \$9,001 - \$12,000
  - f. Number of families with income between \$12,001 - \$16,000
  - g. Number of families with income greater than - \$16,001 a year

Tabulation Request Based Upon 25% Data - cont'd

6. Number of licensed motor vehicle operators
  7. Number of cars per dwelling unit
  8. Tabulation of number of persons born in another State or foreign country by name of State or country (from Question '13 a.)
-

All of these data represented special tabulations for which a "user contract" was negotiated. No delivery was made for the block face unit of aggregation. For technical reasons several of the tabulations of 25% data presented problems arising principally in programming. Thus, the usefulness of the tabulation on education was affected by employing as the universe the total population rather than the population 25 years old and over. Small discrepancies arose between the totals by tract in the 25% tabulations and the 100% tabulations. In general, these discrepancies were limited to Tract 1. Appendix B contains 8 tables all of which, except for the first two, were generated from the 25% data. The special tabulations by traffic zone were part of an experimental user project developed by the Traffic Department of the City of New Haven. Because of staffing difficulties it is understood that the Traffic Department has not made intensive use of census data by traffic zone.

## DIME File

When technical planning for the 1970 census began it was recognized that the use of mail-out/mail-back procedures would require the development of a complete address directory for all cities. Such an address directory should include all street addresses at which dwelling units are located. With the dramatic improvements in computer techniques the capability came into being to develop a geo-coding scheme to identify sides of city blocks and the street addresses falling on each block. Further technical possibilities existed to relate the block faces to a geographic grid system involving the use of latitudinal and longitudinal identifiers for the ends of block faces or for street intersections. In part, the interest in geo-coding schemes arose from the possibility of producing computer generated maps. Essentially, if individual addresses can be identified to block faces and these block faces can be used as "building blocks", census data can then be used effectively for local administrative purposes. In the New Haven experience several administrative areas were in use in various city agencies such as traffic zones (approximately 1/6th tract size), community action and re-development project areas, school attendance areas and telephone cable or market areas.

The first effort of the Bureau of the Census in this area of study was to create a geographic base file for mapping. This was the Address Coding Guide which was generated in mid-1967. (A printout of the Address Coding Guide for Orange, Connecticut is shown on page 62. ) The guide did not prove satisfactory. A new experiential system was developed called DIME (Dual Independent Map Encoding). The DIME system employs numerical encoding of map features which allows for computer editing of the file and

detection of errors. Using the DIME file for the City of New Haven it has been possible to produce a computer generated map and to display statistics on these maps using both the printer and plotter methods. The DIME system, in addition to its mapping capabilities, can be used to geo-code local addresses for the purpose of relating local information to census data. The Bureau of the Census plans to develop DIME files for other cities.

The final version of the DIME file for the City of New Haven was generated in October 1968, and because of the importance of this new development in terms of its use for other cities in 1970, the following technical description of the computer tape format is included.

---

New Haven DIME File Format  
 Street Segment File

---

Char.	Description
1-6	Record Sequence Number
7-24	Street Name (Incl: St. Type & Direction)
25-28	Node A (Low Address Intersection Number)
29-32	Node B (High Address Intersection Number)
33-36	Census Tract on Left Side of Street Segment
37-39	Census Block on Left Side of Street Segment
40-43	Census Tract on Right Side of Street Segment
44-46	Census Block on Right Side of Street Segment
47-50	Low Address of Address Range on Left Side of Street Segment
51-54	High Address of Address Range on Left Side of Street Segment
55	Address Range Code 1 = Odd Address Range 2 = Even Address Range 5 = No Addresses
56-59	Low Address of Address Range on Right Side of Street Segment
60-63	High Address of Address Range on Right Side of Street Segment
64	Address Range Code (same as for Char. 55)
65-69	X Coordinate for Node A (in Conn. State Plane Coordinates - 500,000 ft.)
70-74	Y Coordinate for Node A (in Conn. State Plane Coordinates - 100,000 ft.)
75-79	X Coordinate for Node B (in Conn. State Plane Coordinates - 500,000 ft.)
80-84	Y Coordinate for Node B (in Conn. State Plane Coordinates - 100,000 ft.)

---

The experimental efforts by staff of the Census Use Office in New Haven and co-operative local users have substantially advanced the understanding of technical problems in computerized address guides and their applications. However, the research is only a beginning. In particular, the inability to experiment with actual block face data has left untested one of the major objectives stated by the Bureau of the Census itself; it is doubtful whether the technical or administrative capability will exist in this area when the results of the 1970 census become available. The Bureau of the Census is well aware of the administrative and technical problems which were revealed during the life of the New Haven Census Use Office. The Bureau of the Census has commissioned a review of their experience by Booz Allen & Hamilton, a firm of management consultants. Personnel of the consulting firm have interviewed New Haven data users as a part of their study which will recommend ways of improving the capability and capacity of the Bureau of the Census to respond to the needs of local agencies.

## CHAPTER VI

### POTENTIALS FOR CENSUS DATA IN LAW ENFORCEMENT ADMINISTRATION

#### Relationship to Total Information System

Users of law enforcement data include, in addition to police agencies, social scientists, public administrators, the press, and the public. The recent explosion of interest in law enforcement and the political significance of the "law and order" issue have resulted in proposals for a total information system which would make effective use of the storage and retrieval capabilities of modern electronic data processing equipment. A total information system might be a large-scale set of inputs embracing all the aspects of community life. The experimental program based in New Haven and sponsored by the IBM Corporation sought to lay the base for such a system. However, a combination of different technical problems as well as the political vulnerability of a "data bank" now suggests that an ambitious program is not likely to be implemented. In the law enforcement field many major police agencies now have all of their "internal data" in machine readable form. Such state-wide systems as New York State Identification and Intelligence System (NYSIIS) are attempting to store internal data from many police agencies in one central retrieval system. At this point a NYSIIS-type system is likely to be limited to stolen property information, particularly automobiles, wanted persons, and criminal histories. In January of 1967, the FBI began operating the National Crime

Information Center (NCIC). The NCIC is a computerized information system, national in scope, providing files on stolen vehicles, stolen guns, and wanted persons. The NCIC is accessible to law enforcement agencies equipped with terminals which are able to communicate directly and immediately with NCIC computers.

At this point in time, there appears to be no operable system in law enforcement agencies which provides access to a file of "external data" that is, information not generated by the activities of the law enforcement agency itself. To the extent that police administrators currently make decisions without an adequate data base, the importance of more data through an operational information system will be an advantage. Police administrators, however, seem to feel that their decisions tend to be reasonably effective on the basis of "internal data". In fact, some have stated that census-type information, because of its intermittent character and geographic conventions, cannot be of major assistance in their decision-making processes. Unfortunately, any significant test of the validity of this position was not possible because of the failure to generate block face information in the New Haven research. However, the limited types of data which were generated have provided a useful matrix into which the police data may be fitted.

#### Computer Lookup Program

Part II of this report provides a technical description of the computerized Lookup Program which was developed on an experimental basis in New Haven. Using a Census Bureau DIME file or other address coding system it is possible, by computer, to locate the block face on which a particular street address falls and to identify the nearest intersecting street. A number of police departments have, or are developing, capability of this type: examples are Chicago, Illinois and St. Louis, Missouri.

The New York City Police Department's Project SPRINT (Special Police Radio Inquiry Network) using two IBM System 360, Model 40 computers, will permit the identification of block number, precinct, nearest intersection, and nearest hospital as well as the numbers of three available patrol cars. Sylvania Electronics Systems has developed a system called "Beatfinder" which determines the patrol beat corresponding to the address. Such operating systems will have a short retrieval time. In the case of the New Haven project, more modest objectives were sought. Initially, the computerized lookup procedure was one intended to permit the assigning of complaints to block faces, blocks and census tracts. When the identification of address ranges and intersecting streets is completed the system could be used operationally in the same way as Project SPRINT. The clerical work involved in the identification from maps of the lookup system inputs has been completed for 18 of the 28 tracts in the City of New Haven, but the lack of computer capability at this point has permitted only experimental use of the lookup program.

Tract 6 was used for demonstration purposes and the table on pages 68 to 71 shows the wealth of information available from the Census Pretest of 1967 for each block in the tract. This type of socio-economic information describes many of the characteristics of the area which have relevance to police administration. The map on page 72 shows the configuration of Tract 6. In Appendix II a portion of Tract 6 is shown for which the lookup program was tested. Typical printout from the computerized Lookup Program is shown on page 73. The first line, for example, with an address input of 315 Columbus Avenue retrieves the information that this address is in Tract 6, Block 301.

In addition, Hallock Street is shown as the low intersecting street and Arch is shown as the high intersecting street. The facing tract is Tract 5 and the facing block is Block 101. The printout also shows four examples of incorrect input due to misspellings or incorrect house numbers. The printout indicates in these cases, "Not on File."

The map on page 75 identifies complaints made by street address during the month of November 1967, for Blocks 307 and 310 in Tract 6. An operational system would be able to allocate complaints to block faces and, in turn, relate the complaint information to the socio-economic characteristics of the block face.

#### Police Utilization of Data

In addition to the operating value of a computerized system such as described above, analytical purposes can be served, among which the forecasting of police services demanded is perhaps the most intriguing. Two approaches are possible: one approach is to formulate patterns of demand entirely on the basis of internal data which, in effect, projects police service experience. The report by R. Dean Smith, "Computer Applications in Police Manpower Distribution", was a pioneer effort in indicating potentials of computerized procedures for predicting the need for police service including the development of a weighting system. Essentially, this report extended the classic methods of O.W. Wilson in the development of a manpower allocation scheme for Wichita, Kansas. The St. Louis Police Department's "Allocation of Patrol Manpower Resources" (OLEA Grant #039) describes a more modern system. The information cycle in this system provides data on crime and on calls for service. The number of calls for service in a given area during a definite time period are predicted as well as the time required to service the calls. By setting an acceptable delay time the police administrator may determine his manpower deployment requirements.

Source: Police Department, New Haven City, 1967.

The second approach is illustrated by the study prepared for the Philadelphia Police Department by the Franklin Institute Research Laboratories entitled, "Computer-Aided Crime Prediction in a Metropolitan Area", OLEA Grant 049. In this report, as described in Chapter I , a series of sociological factors were used to supplement the available crime-related factors. The final report for the project indicates that, "The results of the several analyses demonstrate the existence of differences in surrounding conditions for different crime types and give every indication that crime prediction, using a computer based model, can be achieved." Unfortunately, the sociological (neighborhood) conditions surrounding each crime were taken from 1960 census data and thus were seven years out-of-date at the time of the Philadelphia research. It is clearly important to extend these research efforts immediately after 1970 census data become available.

In connection with the New Haven research, a formulation of possible outputs was made accepting the constraints that the use of the data must be meaningful to the police as contrasted with mere academic research; that the use of the data were considered as part of an eventual management information system; and that computer mapping be one form of output display. For data outputs were envisioned: 1) forecast of demand for police services as measured by complaints classified by neighborhood, type of complaint, squad car responding, sex and race of complainant; 2) forecast of the arrests made by police in response to the demand for police service; 3) an assignment listing for foot and motorized beats; 4) the fourth output of the system was to be a test. The test component would compare the forecasted demand against actual experience in order to evaluate the forecasting method by means of a scoring system. This last aspect of the

research is critical because "intuitive" forecasting by experienced senior police commanders may be sufficiently precise so as to make the investment in a computerized system unjustified. There appears to be some evidence in this direction in the case of the Philadelphia experiment.

### Techniques

Given the weaknesses in the raw data, particularly in respect to complaint information, many on-going analytical systems appropriate for police use should use the simplest statistical techniques. The most sophisticated methods that appear appropriate are those of multiple correlation by means of which the various socio-economic factors may be assessed. There is a close correlation between many of the socio-economic characteristics which can be measured through census data. It is probably that continued research will permit the elimination of some of the variables on the ground that they contribute little as "explanatory variables". Stepwise regression, for which "canned programs" are available in most EDP systems, is a useful technique in evaluation of the comparative importance of variables. Multi-dimensional analysis was used in the Philadelphia study to analyze the model for burglaries. Multiple regression analysis results were not satisfactory as a predictive tool in the Philadelphia investigation. Unfortunately, there was no opportunity to test statistical techniques with the New Haven data. Any analytical system is dependent upon its data input and all the experiments recorded in the literature have not been able to assess the validity of the internal data on complaints. Auditing procedures such as those employed in St. Louis, Missouri, address themselves to honesty in recording all complaints rather than the much more difficult question of the relationship between complaints and the universe of crime.

In connection with the work of the National Crime Commission of 1966, the first intensive attempts were made to use surveys of samples of the general public for estimating the incidence of crime. Surveys in Washington, D.C. suggested that police statistics grossly underenumerated actual incidence of crime. Respondents in a national survey report being victimized by crime more than twice as frequently as would be expected on the basis of the Uniform Crime Reports "Crime Index". Much more research will be needed before any quantitative judgment can be made about the differential characteristics of under-reporting between neighborhoods and population groups.

#### Computer Mapping

From the point of view of a police administrator, computer output displayed in the form of a map has considerable attraction. Technical capacity exists to produce maps displayed on a cathode ray tube or in hard copy format. One can realistically accept the dream of a real time system which will generate displays in the form of maps. Manual graphics produced by draftsmen are now rapidly being replaced by computer graphics. Four types of computer generated maps are shown on page 79, they are Density, Values, Conformal and Geospace plotter maps. The Conformal, or SYMAP is a continuing tool in the St. Louis Police Department. The SYMAP has a large number of statistical support factors which permit calculation of means, standard deviations, histograms, and percentile groups all within the same mapping package. On page 80, a Geospace plotter map generated by the New Haven Census Use Study is shown. This indicates the percent of non-white population. The plotter map simulates map drawing as done by draftsmen.

## 1970 Census Plans

As this report has made clear, the block face data capability of the New Haven Census Pretest could not be tested because no block face data were released. This development appears to have been a consequence of a decision in the Washington, D.C. Office in respect to confidentiality policies and technical difficulties. Under the legislative mandates given by the Congress to the Bureau of the Census, census data is "confidential".

In practice, the interpretation of confidentiality rules is quite different because it must represent a balance between confidentiality and usability. In general, as was the case for the 25% Summary tapes provided by the Bureau of the Census to this project, if a block contained fewer than 25 households all cells for that block were zeroed out. In the case of the 100% complete count data, a minimum of five households was regarded as necessary. When an effort is made to breakdown the information to the block face level the confidentiality rule becomes even more restrictive. The map on page 82 represents Tract 16 with block face data on the number of households. This map was an experimental effort by the Census Use Office. It will be noted that many of the block faces in this tract have less than the minimum number of households. Therefore, it would be necessary to aggregate block faces in order to make possible the printing-out of data on the characteristics of the households. The staff of this project proposed to the Bureau of the Census the following four statements in respect to aggregating block face data.

1. The Census Tract boundary is not to be crossed by any aggregation procedure. The only exception would occur because of the method of aggregation.
2. Both sides of the street are to be aggregated as a tabulation unit. As a result the aggregated unit consists of a street segment between two cross-streets, not T - intersections.
3. The tabulation begins at a full intersection and aggregation continues until at least 5 households, the number needed to override the rule on confidentiality for 100% data, are tabulated.
4. If the tally is insufficient when the street comes to an end or meets the census tract boundary, the aggregation is to be dropped; it is recognized that this data would be lost.

From the point of view of the police administrator an aggregation policy which would combine facing block faces along a street would be satisfactory. Unfortunately, the Bureau of the Census was not in a position to provide any experimental data to test out the proposed principles in respect to block face aggregates. Because of the importance of this failure in terms of the initial objectives of this report, the following statement from the Bureau of the Census is relevant:

The question concerning the possibility of obtaining block face tabulations for New Haven remains negative, there are no plans at present to tabulate the New Haven Special Census data by block face. Special block face tabulations could have been made available, official policy allows such release; however, we do not now have the necessary computer systems to make such tabulations.

The Census Use Study plans to begin research into the problems and technology needed to provide data at the block face level. Such research will probably begin in late 1969 and may be conducted in Los Angeles by the Southern California Regional Information Study (SCRIS), or become a project of the New Haven Census Use Study at about that same time. We anticipate that research into the problems of tabulating block face statistics will be concluded and documented in time for use with 1970 census data. Hopefully, we will develop from this research a workable system for extracting such tabulations from our basic record tapes.

Our present plan is to initiate our research with a study of the feasibility of producing such block face statistics on a street segment basis, i.e., data would be derived for a combination of sequential street segments (both sides of a street between intersections). The number of street segments in each series will be determined by confidentiality rules.

It has been indicated that the Summary tapes which will be made available to users subsequent to the 1970 census will not contain the block face data. Aspects of the usability of census data by law enforcement agencies were examined by law enforcement work groups which met with the staff of the Bureau of the Census on March 4-5, 1968. The report "National Needs for Criminal Justice Statistics" which gives the results of their deliberations was issued by the Bureau of the Census in August 1968.

PART II

## COMPUTERIZED LOCATIONAL LOOK-UP PROCEDURES

### Background

With the development of electronic data processing equipment (EDP) police administrators recognized the potential of EDP for efficient utilization of manpower. Some of the earliest applications of EDP were in terms of obtaining information on wanted persons, auto licenses, serial numbers and the like, more quickly and efficiently than with a manual search. EDP was also used in such statistical applications as the tabulation and analysis of crime reports, calls for service, personnel records and budgetary administration. In these applications speed of information retrieval was not as critical.

Since it is selfevident that police manpower, as a scarce commodity, should be allocated in space and time in such a manner as to correlate effectively with calls for service, the capability of EDP is attractive in this area. In theory, a "real time" system would permit immediate matching of available manpower with calls for service. There are two dimensions involved, one of time and the other of space. The time dimension involves such questions as appropriate work schedules such as the three or four platoon system, patterns of days off, sickness, special assignments, and other variables which determine the number of men actually available at any point in time to respond to calls for service. This aspect of manpower allocation was not considered in this research project.

As has been pointed out in Chapter III, the size and comparatively unsophisticated procedures in the New Haven Police Department meant that an elaborate evaluation of manpower management policies would not be of high priority. Until recently the basic statistical data were not available to the Chief of the Department.

In respect to the second dimension, that of space, it has long been evident to police administrators that the distribution of calls for service is uneven throughout the patrol area. This research project has been primarily focussed upon the spatial distribution of police activity. Even aside from the special aspects of the availability of block face data as discussed in Chapter I, police manpower allocation is necessarily related to block faces. Thus, in Chicago and St. Louis the police departments' geographic schemes to define areas have been developed and are operational. In Chicago the location code is based on the division of the city into four parts or quadrants. The location code is written on the radio call cards. Lists of diagonal streets are provided to officers in the patrol cards and also district maps can be used to look up the beat of occurrence which is also entered on the radio call card. In St. Louis geographic units called "Pauly" areas have been established. There are 480 of these small geographic areas each having a unique number. The average size of a Pauly area is from 9-12 city blocks. While the Pauly area system is primarily for data collection, it lent itself to incorporation into a computer file system. As the computer center developed in the St. Louis Police Department the "New Location Code" was developed. This system related the coded address to various geographic areas. The coding system, known as the Location Code, uses only numbers; each street is assigned a number so that the computer's system location for a typical street address consists of the house number, a slash, and a "Q" number of

the street. The Location Code for an intersection is made by writing the "Q" for one<sup>1</sup> street and "X" to indicate an intersection and a "Q" for the other street.

In New York City Project SPRINT (Special Police Radio Inquiry Network), when implemented, will determine block number, precinct, nearest intersection, and nearest hospital as well as the numbers of three available patrol cars for each call for assistance. SPRINT will use two IBM System 360 Model 40 to handle the workload.

#### New Haven Requirements

As a by-product of the introduction of a Central Complaint Desk in the New Haven Police Department and with the development by the Bureau of the Census of the DIME file, it seemed desirable to allocate some of the resources made available by this research grant to develop a computerized system for relating addresses of calls for service and nearest intersecting streets. While the New Haven Police Department has no present in-house computer capability, the management in the Department is committed to obtain such capability and to relate the Central Complaint Desk procedures to a "real time" system. In addition, the basic philosophy is that the computer system should also have been considered in this report. Since block face information availability was the initial premise of this report, the planning effort allocated to the computer system was predicated upon the block face as the smallest unit of aggregation. As a practical matter, from the point of view of police manpower allocation and statistical analyses, the block face is

<sup>1</sup>  
An extensive description of the St. Louis procedure is included in the report, "Allocation of Patrol Manpower Resources in the St. Louis Police Department", July, 1966, Volumes I and II.

a logical unit. Thus, as has been pointed out in the earlier discussions of Census Bureau policies, even if socio-economic data will not be available by block face the faces can be aggregated to create whole blocks. Thus, on the basis of all these considerations, a computerized system was structured which provides the capability of relating any street address to the block face on which it falls and relating the street address to the nearest intersecting street. As a by-product block and tract number are also identified. It is felt that this geographical identifier system will meet the requirements of both current operations as well as statistical analyses both for internal police data and external socio-economic data. At this point, of course, the New Haven Police Department does not have computer capability to make the system operational nor would research resources permit the preparation of completed in-put to the system.

#### Geographic Identifiers

As discussed in Chapter V, the Census Bureau DIME file was an experimental system developed by the Bureau after an attempt to use the Census Bureau's Address Coding Guide to create the geographic base file for mapping did not prove entirely satisfactory. The attempt to use geographic coordinates (latitude and longitude measurements) obtained on the basis of a digitizing procedure encountered a whole range of  
2  
difficulties.

2  
The kinds of geographic coordinate systems which may be used and aspects of digitizing are considered in the report, "Geo-Coding Techniques for Small Area Data", pp. 50, 1967.

From the point of view of police administration, there would appear to be no need for a coordinate system (latitude/longitude) since the natural description for an event is the street address and the nearest intersecting street. A simple system for the identification of block faces, suggested by Miss Dorothy A. Walsh, utilizes the number of the facing block. Thus, if Block 309 in Tract 6 faces Block 310 in Tract 8, the Walsh identifier is 06-309-08-310. On this basis each block face is uniquely identified. Special problems arise, of course, in connection with geographical features other than blocks: blocks facing more than one block, multiple block intersections, etc. However, the identification system can be adapted without abandoning the essentially simple concept. In addition, using the Walsh identifiers, it is easy to aggregate all the block faces (usually four in number) to make a complete block because the block number is incorporated into each block face identifier. Map II-1 which shows a part of Tract 6 illustrates the block face identification method.

In order to provide a Look-up procedure to go from street address to block face it is necessary to have a range of addresses from low address to high address for each block face. Since the original version of the Bureau of the Census' Address Coding Guide presented a large number of operational problems it was decided, for police department purposes, to generate manually a list of all block faces with low and high address range. This was done working from Sanborn Maps with field verification where difficulties were encountered. This procedure generated a listing showing street name, low address, high address, tract and block number, facing tract and block number. In certain cases there would be more than one facing tract and block number. The following is an example of the type of listing prepared in this process:

Code	Street	Low Add.	High Add.	Tract & Block	Facing Tract & Block	Intersecting Streets	
						Low	High
9	Sylvan Ave	1	19	06101	06107	Howard Ave	Vernon St
9	Sylvan Ave	21	35	06101	06106	Vernon St	Ward St
9	Ward St	163	299	06101	06102	Sylvan Ave	Legion Ave
9	Legion Ave	20	72	06101	07303	Howard Ave	Ward St
9	Howard Ave	900	922	06101	03102	Sylvan Ave	Legion Ave

Input data for the following tracts have been completed: Tracts 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, and 27 (10 of the 28 tracts in the City of New Haven have not been completed). In determining the address ranges Sanborn Maps are essential. The Sanborn Map Company provides an up-dating service about once a year on the basis of field checks which include changes of house numbers and street names.

From the input of block face data as illustrated above, a Street/Tract/Block Dictionary can be prepared and placed on computer tape or disk storage. Such a file can be up-dated and corrected quite easily.

3

The Sanborn Map Company of Pelham, New York, has block maps of virtually every city in the United States. These maps may be purchased or rented and show certain characteristics of each building such as details of construction and use.

## USERS' GUIDE TO LOOKUPAD PROGRAM

Since the approach to a computerized Lookup Program in New Haven may lend itself to the needs of other police departments, a detailed statement of the programs with flow charts is included. The descriptive material which follows includes a Users' Guide to the LOOKUPAD Program, the Street/Tract/Block Dictionary Up-Date Program, the Program Narrative and related flow charts. The technical guidance in connection with the development of this program was provided by the staff of Advanced Computer Techniques Corporation (ACT). Work on the program was directed by Miss Dorothy A. Walsh, Vice President of ACT, and Miss Phyllis Winslow, Mr. Michael J. Wichura and Miss Patricia Goglia served from time to time as programmers. The responsibility of ACT was limited to consulting assistance. The computer program has been run on an experimental basis for a part of Tract 6 and the results of this experiment were discussed in Chapter VI.

## USERS' GUIDE TO LOOKUPAD PROGRAM

PREPARED FOR THE METROPOLITAN POLICE DEPARTMENT

THE CITY OF NEW HAVEN

### A. Background and Development

#### I. Origin and Purpose

This program was prepared as part of a study carried out in New Haven, Connecticut to determine the usefulness of census data in police tasks. The orientation of the program is therefore toward census identifiers for tabulated socio-economic data. In particular, the census tracts as they are defined for New Haven serve as a means of grouping results.

Within the census tract statistics for population and other socio-economic variables are gathered on the basis of city blocks. Thus, city block identifiers are also associated with tabulated results.

An increasing awareness of specific needs for police service in areas having a particular socio-economic character lent interest to investigating the possibility of identifying and measuring relationships between recognizable characteristics and police activity. The possibility of predicting police needs, and more important, the possibility of anticipating and inhibiting the development of socio-economic characteristics recognized as undesirable, stimulated efforts to utilize in police service information gathered by the Bureau of the Census.

Certain police data may, for many purposes, be grouped into the census tract, (groups of blocks combined by the Bureau of the Census). For other purposes such coarse grouping is undesirable because it may tend to hide rather than reveal important relationships.

The main concern about such grouping of police data lies, however, in the fact that police data are normally received on an individual location basis -- dwelling, shop, etc. Most police departments have report forms which use street addresses.

It became of interest, therefore, to devise a means of translating the street address locators automatically into their census area equivalents.

To this end an identifying code for street addresses was designed to duplicate census data identifiers. A block number and census tract number are associated with the street address numbers on the face of a single block. All faces of a block must be considered in using census data.

In using police data it is often desirable to have a finer breakdown. Individual block faces are of interest. To provide this sort of breakdown for New Haven a block face identifier was developed - a combination of a block and tract number for the face on which a street address is found followed by the block and tract number of the opposite side of that street.

## II. Design Environment

A set of programs was designed to effect the translation from street address form to block face form.

The programs are designed to provide the New Haven Police Department with an automatic means of directly relating its street address complaint data to the census data as well as to block faces.

The set of programs needed is intended to perform, generally, the following functions:

- a. to prepare and maintain a dictionary of street address numbers and related block face identifiers for retention on tape or disk (this program was written in AUTOCODER);
- b. to carry out a look-up in the Dictionary to match street addresses on complaint records;
- c. to tabulate and report desired complaint information,

These factors inhibited to a degree the design and implementation of specific data processing applications within the time period allowed. The original intent was a set of programs to perform a number of inter-related functions. This intent has been only partially accomplished.

## III. Implementation Environment

Implementation of the systems was carried out during the development of the census data it was intended to use. The period of preparation of the census data coincided with a period of change in the Police Department (see Chapter III) forms of reporting complaints in New Haven.

## B. Description of the LOOKUPAD Program

### I. Purpose

The purpose of the LOOKUPAD Program is to search in a dictionary of street address numbers and associated block and tract identifiers to find the identifiers for a given address and to print that information.

### II. Operating Environment

LOOKUPAD is written in COBOL for the IBM 1401 computer. It uses: tapes, the card reader, the printer.

Hardware requirements: 12K 1401  
two 7330 Magnetic Tape Units  
Typewriter input (1407)  
Printer 1403  
Card Read Punch 1402  
Console inquiry station 1407

Software requirements: COBOL Compiler Med.

### III. Input

1. Input to LOOKUPAD is a standard New Haven Police complaint card (see Chapter III). The only fields used are:

<u>Column</u>	<u>Contents</u>
17-20	House number
21-37	Street name

2. A code card is required to indicate whether addresses are odd or even. This card contains an O (Odd) or an E (Even) in Column 1.

#### IV. Output

Output from LOOKUPAD is in two forms.

1. There is a card in the following form:

<u>Column</u>	<u>Contents</u>
1-4	House number
5-20	Street name
21-22	Not used
23-27	Tract number
28-34	Low intersecting street
35-41	High intersecting street
42-46	Facing tract number
47-80	Not used

2. A printed report is produced in the following format :

<u>House No.</u>	<u>Street Name</u>	<u>Tract #</u>	<u>Low Intersecting St.</u>	<u>High Intersecting St.</u>	<u>Facing Tract #</u>
0315	Columbus Ave	06301	Hallock St	Arch St	05101
0367	Columbus Ave	06302	Arch St	Frank St	06101
0399	Columbus Ave	06303	White St	Redfield St	05102
0477	Columbus Ave	06303	Not on file	Redfield St	05102
0417	Congress Ave	06201	Howard Ave	Vernon St	06206

#### V. Procedure for Use

To use LOOKUPAD the Dictionary must be on tape and data cards prepared as described above. Data cards, sorted alphabetically on street name follow the code card and program cards in the card reader. Cards are punched and the report printed.

The program must be run once for even, once for odd addresses.

## C. Discussion and Recommendations

### I. LOOKUPAD Revisions

Characteristics of LOOKUPAD are not optimum. Use of tape for the Dictionary is not satisfactory because computer tape is treated sequentially. The addresses looked up might begin, for example, at M thus requiring the reading of all preceding street information. Sorting could be eliminated by the use of disk storage which would provide random access capability.

A change to allow odd and even lookup is also desirable.

### II. Programs Related to LOOKUPAD

The proposed complete set of programs should be implemented to take advantage of LOOKUPAD. Specifically, programs should be prepared to:

- a. set up complaint record information based on census locators;
- b. add desired census data to cards with the identifiers in the Dictionary;
- c. prepare a new complaint record containing the original police data and the new locator information.

### III. Extensions of the System to Other Cities

The general concepts embodied in the programs designed for the City of New Haven are intended to provide a statistical framework for current police data. Complaint information is to be coded on a current basis and related to pertinent socio-economic factors.

The techniques of location of complaint site, in particular the ability to extrapolate block face identifiers to street intersection identifiers, have further implications for police management. Dispatching police manpower would be facilitated by the use of locator codes, particularized to the intersection level. Under special operating conditions the codes could be used as a confidential dispatching method.

## STREET/TRACT BLOCK DICTIONARY UPDATE PROGRAM

### 1. Street/Tract - Block Dictionary - General Description

The Street/Tract - Block Dictionary is a tape file containing information on the streets of New Haven. For a given street, there is included in the Dictionary, first, a description of the intersections along the street, and second, descriptions of the segments between these intersections.

An intersection is described by means of an "I Record", which is made up of:

1. the code letter "I" (standing for Intersection);
2. the name of the main street;
3. a sequence number, which gives the relative order of the intersection in the direction of increasing house numbers along the main street;
4. a two-digit intersection code. The first (respectively second) digit is the number of intersecting streets at the intersection on the odd (respectively even) numbered side of the main street;
5. the names of the intersecting streets at the intersection.

A segment of the main street between two intersections is described by either an "O" record or an "E" record, depending on whether the odd or even numbered side of the street is being described. O/E records are made up of:

1. the code letter O for an "O Record", E for an "E Record";
2. the name of the main street;
3. the sequence numbers of the intersections at the low and high (in the sense of increasing house numbers) ends of the segment;
4. the names of the intersecting streets at the low and high ends of the segment. If there are two intersecting streets at one end of the segment, the name of the closer street is needed. If there are no streets at one end of the segment the name of the (closer) intersecting street at the same end of the segment directly across the main street is used;
5. the numbers of the tract and block of which the segment is a part;
6. the numbers of the tract and block of which the segment directly across the main street is a part;
7. the low and high house numbers on the segment, if any;
8. a characterization of the low and high locations on the segment.

If no house numbers (item 7) are given, this information must be present; otherwise it may be omitted.

For a given main street I records are stored sequentially according to sequence numbers of the corresponding intersections, and are followed immediately by pairs of O and E records which are stored sequentially according to the corresponding pairs of sequence numbers of their low and high intersections. The main streets themselves are stored in alphabetical order.

## 2. The Update Program - General Description

The Street/Tract - Block Dictionary Update Program is used to insert new records into and/or to modify or delete records from the Dictionary. Updating is governed by control cards similar to the I, D, and E records of the Dictionary. The Update Program produces a revised Dictionary (on tape) and a printed record showing the update cards and the Dictionary entries for streets for which changes have been made.

The Update Program makes numerous checks on the information it processes. Entries on the update cards are scrutinized for errors. Update cards found to contain mistakes are rejected and not used in the Dictionary. Several checks are made on the totality of O/E records for a given street, including a check for missing entries. All errors detected by the update program are noted in the printed output.

## 3. Update Card Formats

### A. I Cards

"I" cards are used to enter, modify, or delete information about an intersection along a main street. The format of an I card is as follows:

Column	1	I
Columns	2-17	main street name
Columns	18-20	sequence number
Columns	21-22	intersection type
Column	23	control card action (I, M, or D)
Column	24	blank
Columns	25-80	intersecting street names

The "sequence number" does not have to be purely numeric; each digit can be any of the 64 characters read by the 1401. Sequence numbers are ordered using the ordering of characters built into the 1401 (the so-called collating sequence). In particular, 01 blank before 01A which, in turn, comes before 01Z which, in turn, comes before 010.

Column 21 is the number of intersecting streets at the intersection on the odd numbered side of the main street; Column 22 is the number of intersecting streets at the intersection on the even numbered side of the street. Each of these numbers must be either 0, 1, or 2. In the rare instance when there are more than two intersecting streets on one side of the main street at the intersection, only the first and last should be read. The intersection type may not be 00.

Columns 25-80 provide space for variable-length fields for the names of four intersecting streets at the intersection. In order, these streets are:

- a. the first intersecting street, if any, on the odd numbered side of the main street;
- b. the last intersecting street on the odd numbered side of the street, if there is more than one such street;
- c. the first intersecting street, if any, on the even numbered side of the main street;
- d. the last intersecting street on the even numbered side of the street, if there is more than one such street.

The names of these streets must be separated by commas, and the fourth name must be followed by a period. No other periods may be used. No field may begin with a leading blank, and no field may be longer than 16 characters. If a field does not apply (for instance, if there is only one intersecting street at the intersection on the odd-numbered side of the street), then it, but not the surrounding commas and/or period, is omitted.

#### B. O/E Cards

O and E cards are used to enter or modify information on a segment of a main street between two consecutive intersections. The format for an O/E card is as follows:

Column	1	O or E
Columns	2-17	main street name
Columns	18-33	low intersecting street
Columns	34-49	high intersecting street
Columns	50-51	tract number
Columns	52-54	block number
Columns	55-56	facing tract number
Columns	57-59	facing block number
Columns	60-63	low address
Columns	64-67	high address
Columns	68-70	low location
Columns	71-73	high location
Columns	74-80	not used

Column 1 contains an O (respectively E) if the card is used to describe the odd (respectively even) numbered side of the main street.

Throughout, "low" and "high" are to be interpreted in the sense of increasing house numbers. The low intersecting street (LIST) is determined as follows: if there is just one intersecting street at the low end of the segment, it is the LIST; if there are two or more intersecting streets at the low end of the segment, the last one is the LIST; if there are no intersecting streets at the low end of the segment, the LIST is the last intersecting street at the low end of the segment directly across the main street.

The high intersecting street (HIST) is determined as follows: if there is just one intersecting street at the high end of the segment, it is the HIST; if there are two or more intersecting streets at the high end of the segment, the first is the HIST; if there are no intersecting streets at the high end of the segment, the HIST is the first intersecting street at the high end of the segment directly across the main street.

The same name may not be used for intersecting streets at different intersections along the same main street. Even if two intersecting streets at different intersections have, in fact, the same name, a distribution between them must be made so far as the Dictionary is concerned. The tract and block are the tract and block of which the segment is a part. The facing tract and block are the tract and block of which the segment directly across the main street is a part.

The low (respectively high) address is the lowest (respectively highest) house number on the segment. If there are no house numbers at all on the segment, the low and high addresses are omitted; otherwise both must be present. Leading zeros, if needed, must be supplied to make each address 4 digits in length.

The low and high locations, if used, must be one of the following symbols:

<u>Symbol</u>	<u>Meaning</u>
PK	Park
TPK	Turnpike
PKG	Parking
RIV	River
AIR	Airport
CL	
VIA	Viaduct
RR	Railroad
EL	
NFH	
CEM	Cemetery
HAR	Harbor

Low and high locations must be used if no addresses are given; otherwise these fields are optional.

#### 4. Uses of Update Cards

##### A. To Insert a Street in the Dictionary

An I card must be given for each intersection. These cards contain an I (for Insert) in Column 23, and they must be ordered by their sequence numbers (Columns 18-20). After all the I cards for the street, O and E cards for the various segments of the street between the intersections specified by the I cards may be given. These O/E cards may be in any order. It is possible to give only I cards or only O/E cards -- in the first case, the printed summary of the update will indicate that information is missing in all the O/E records in the Dictionary for the street; in the second case, the O/E cards will be checked for possible errors, but will not be incorporated into the Dictionary.

##### B. To Modify an Intersection on a Street in the Dictionary

An I card must be given which has the same main street name and sequence number as the I record in the Dictionary. Column 23 must contain an M (for Modify). The information in the other fields replaces the other information in the I record in the Dictionary.

##### C. To Delete an Intersection on a Street in the Dictionary

An I card must be given which has the same main street name and sequence number as the intersection in the Dictionary. Column 23 must contain a D (for Delete). The remaining fields are not required.

##### D. To Insert an Intersection on a Street in the Dictionary

An I card must be given which has the appropriate main street name. Column 23 must contain an I (for Insert). The sequence number of the intersection must lie between the (Dictionary) sequence numbers of the intersections between which the intersection is to be inserted (since the last character of a Dictionary sequence number is always a blank, as many as 63 intersections could be inserted between two consecutive intersections in the Dictionary). If the intersection is to be inserted before the first intersection in the Dictionary, the I card must have a sequence number less than 01 blank. If the intersection is to be inserted after the last intersection in the Dictionary, the I card must have a sequence number greater than that of the last I record in the Dictionary.

##### E. To Insert an O/E record on a Street in the Dictionary

An O/E card with the appropriate main street name, together with the other fields, must be given.

F. To Modify an O/E Record on a Street in the Dictionary

An appropriate O/E card must be given. The information on this card replaces the information in the corresponding record.

G. To Delete All Information on a Street in the Dictionary

All (or all but one) of the intersections (I records) along the street must be deleted using I cards with a D in Column 23 (see C).

H. To Get the Records in the Dictionary on a Street

There is no special provision for this. However, giving a single update card with an error on it causes the update program to reject the card and list the dictionary records for the corresponding street together with error messages. For example, one can give an I card with only Columns 1-17 filled in. A listing of the records on a street, together with error messages, will at any rate, be available from the previous update action on the street.

# 6. Examples

Figure 1 depicts part of Columbus Avenue. The intersecting streets are labelled as are the tract/block numbers of the various segments. High and low house numbers are indicated.

Figure 1

(a) This part of Columbus Avenue could be inserted into the Dictionary by using the following update cards:

O	Columbus Ave	Arch St	Frank St	063020510103650369
E	Columbus Ave	Arch St	Frank St	0510106302
O	Columbus Ave	Frank St	White St	063020510203730393
E	Columbus Ave	Frank St	White St	0510206302
O	Columbus Ave	White St	Redfield St	063030510203950421
E	Columbus Ave	White St	Redfield St	0510206303

(b) Suppose that on the fourth I card, White St were misspelled as Wjite St and that this (mistaken) entry was made in the Dictionary. This situation could be rectified during a subsequent update run by giving the following update card:

I Columbus Ave                      04 10M White St,,,. .

together with the four O/E cards with White St as an intersecting street (these cards would have been rejected during the original update run, since at that time White St would not have been recognized by the update program as an intersecting street name).

(c) Suppose that at some future date, Redfield St were removed and a large building complex were put up on the combined block. This change could be accounted for insofar as it affects Columbus Ave by giving the following I card:

I Columbus Ave                      05 D

together with an O and an E card between White St and West St. Note that the old O/E records between White St and Redfield St and between Redfield St and West St would automatically be removed by the update program.

(d) Suppose that it were discovered that the high address between Hallock St and Arch St were actually 353 instead of 361. Then this item would be corrected by giving the following update card:

O Columbus Ave                      Hallock St. Arch St 063010510103130353

## 7. Making an Update Run

Update action can (and should) be carried out on several streets during a single update run. Needed for an update run are:

1. the update program (object deck);
2. the update control cards;
3. a card with Z's in Columns 1 through 80 (Z in 2 through 17 will do);
4. the previous street/tract block-dictionary;
5. a blank tape to contain the reviewed Street/Tract Block-Dictionary.

The order of the update cards is important. If a street is being inserted in the Dictionary, the cards for that street must be in the order specified in 4. A. If a street already in the Dictionary is to be altered during the update run, the update cards for that street must be given in the following order: first, all I cards (whether they have I, M, or D actions) ordered by their sequence numbers; second, all O/E cards (for which the order is irrelevant). The update cards for the various streets must be ordered alphabetically by the name of the main street.

The update program, followed by the update cards, followed by the Z's card, should be placed in read hopper and loaded. Immediately after loading, the update program types the message:

"Mount tape bearing old Dictionary on Drive 2, tape for updated Dictionary on Drive 1, check that last update card is all Z's, then press START"

on console typewriter and pauses. The tapes may be mounted at this time (or earlier). Once started, the update program processes the update cards, producing a revised Dictionary on tape Drive 1 and a printout of the results of the update run. After (and only after) reading the Z's card, the update program terminates, rewinds (but does not unload) the tapes and types the following message on the console typewriter.

"Update completed. New Dictionary is on Drive 1."

The program is, at this point, in a temporary halt. Pressing START causes the program to begin again (so that it is possible to follow one update run immediately by another simply by switching the tape drives). Once the tapes are unloaded, the user must label them by hand; the update program does not write or process any tape labels.

Before the update program is run for the first time, an initial Dictionary tape (containing no streets) must be created having the proper block size and terminating characters (9's). An auxiliary program to prepare such a tape has been written.

#### 8. The Update Monitor

The update program produces a printed record of the revisions made in the Dictionary during the course of an update run. If no alterations are made on a street, all the records on the street are transferred to the new Dictionary and the printout contains the message:

"\*\*\*\*street name included as is".

If alterations are made on a street, the update monitor prints out the heading:

"\*\*\*\*street name",

followed by:

1. the heading "update cards";
2. the update records and either
3. the heading "dictionary entries for street name"
4. or the dictionary records for the street;
5. or the message, "no entries made for street name".

If at least two acceptable I records are obtained, either from tape or from cards, entries are made for the street in the new Dictionary and (3) and (4) appear in the output; otherwise no entries are made for the street and (5) appears in the output. Errors detected by the update program are noted in the righthand margin of the printout.

Update cards are printed in an expanded format to make them easier to read. For I cards, four fixed width fields, separated by blanks, are used to display the names of the intersecting streets at the intersection. For O/E cards, the various fields are separated by one or more blanks.

Dictionary I records are printed on the same format used to print I cards, except that the action field (Column 23 on I cards) is blank. The sequence number of an I record is a three character field, the third character of which is a blank. Dictionary O/E records are printed in the same format used to print O/E cards, except that between the names of the main street and the low intersecting street there are included the sequence numbers of the low and high intersections on the segment, separated by a hyphen; since the last character of Dictionary sequence numbers is a blank, only the first two characters of the sequence number are used.

#### 9. Error Messages

When an error is detected on an update card or in a Dictionary record, the update program makes note of this error in the righthand margin of the corresponding line of the printout. The error messages and their significance are as follows:

- EO1    Column 23 is not an allowable action character - I, M, or D.  
The card is rejected after checking for EO8 and EO9.
- EO2    This card has the wrong number of commas (should be 3) separating  
the names of the intersecting streets. The card is rejected after  
checking for EO8 and EO9.
- EO3    The leading character of the name of some intersecting street is  
a blank. The card is rejected after checking for EO8 and EO9.
- EO4    Some intersecting street names exceed 16 characters. The card  
is rejected after checking for EO8 and EO9.
- EO5    The only intersecting street on the odd numbered side of the street  
at the intersection is given in the second rather than the first street  
name field. The card is rejected after checking for EO6, EO7,  
EO8 and EO9.
- EO6    The only intersecting street at the intersection on the even  
numbered side of the main street is given in the fourth rather  
than the third street name field. The card is rejected after  
checking for EO7, EO8, and EO9.

- EO7 The numbers of intersecting streets at the intersection on the odd and even numbered side of the main street do not agree with the specified intersection type. The card is rejected after checking for EO8 and EO9.
- EO8 The sequence number of the I card does not exceed that of the previous error-free I card for the same street. The card is rejected after checking for EO9.
- EO9 At least one O or E card for the same street has preceded this I card. The card is rejected immediately.
- E10 The sequence number of this I card coincides with the sequence number of an I record in the Dictionary for the street, but the action field (column 23) is not M or D. The card is immediately rejected and the tape record is transferred to the output tape.
- E11 The sequence number of this I card does not coincide with the sequence number of any I record in the Dictionary for the same (main) street, but the action field (column 23) is not an I. The card is rejected immediately.

All O/E cards are checked for errors E20 through E44, where appropriate. Cards with errors are rejected.

- E20 The tract-block/facing street block field is not purely numeric.
- E21 The low address field is not blank but is not purely numeric.
- E22 The low address is not of the correct parity (odd for an O card, even for an E card).
- E23 A low address is given but the high address field is not purely numeric.
- E24 The high address is not of the correct parity (odd for an O card, even for an E card).
- E25 The high address does not exceed or equal the low address.
- E26 No low address is given, but the high address field is not blank.
- E27 No low address is given, but the high location field is blank.
- E28 No low address is given, but the low location field is blank.
- E29 The high location field is not a valid symbol.
- E30 The low location field is not a valid symbol.

- E41 Fewer than two I records were developed for the main street. The card is rejected immediately.
- E42 The name of the low intersecting street does not appear among the names of the intersecting streets in the I records.
- E43 The name of the high intersecting street does not appear among the names of the intersecting streets in the I records.
- E44 The low/high intersecting street pairs for this O/E card does not correspond to any of those developed from the I records for the street (this error will arise whenever intersecting streets at different intersections along the main street have the same name).
- E50 The tract-block/facing tract-block and low, high addresses and/or low, high location fields are missing from this O/E record. No further checks are made on the record.
- E51 There is no intersecting street actually present at the low end of this segment but there is a change in the tract-block field from the previous record with the same parity. The record is checked for E53 and, if an E record, for E54.
- E52 An intersecting street is actually present at the low end of this segment, but there is no change in the tract-block field from the previous record with the same parity. The record is checked for E53, and if an E record, for E54.
- E53 The low street number on this segment does not exceed the high street number of the previous segment with street numbers on the same side of the main street.
- E54 The tract-block/facing tract-block field of this record and that of the preceding O record are not consistent.
- E60 The main street name of this update card precedes the main street name of update cards already processed. The card is rejected immediately and printed as is.
- E61 The first column of this update card does not contain an I, O, or E. The card is rejected immediately and printed as is.

#### 10. Format of the Dictionary Tape

All records on the Dictionary are 95 characters in length. The first 94 characters are identical to the first 94 characters in the printout of the record (the code letter is the first character). The 95th character is a record mark. The records are blocked four to a block.

Main streets are included in the Dictionary in alphabetical order. For each street, I records come first, ordered by sequence number, and are followed by pairs of O and E records, ordered by the sequence numbers of their low and high intersections. The arrangement of I, O, and E records is exactly that of these records on the printout. The I records of a street follow immediately the O/E records of the preceding street.

The last significant (as opposed to padded) record in the Dictionary has 9's in the street name field (characters 2 through 17). This record is used to signal the end of street records on the Dictionary tape.

Tapes are handled by standard IOCS routines. No labels are used, nor are any of the tape error options available in the DTF macro.

## PROGRAM NARRATIVE

### Purpose

The purpose of this program is to find the tract and block number that correspond to a given address and to print that information in a report and punch it on a card. The inputs are the house number and street name information on the Complaint code cards and the Master Dictionary File on tape. The outputs are a printed report and punched cards.

### Initial Procedure

This program (LOOKUPAD) was written in COBOL and run on an IBM 1401 computer. With this model computer the original program deck is compiled and an object deck is punched out. When the program is executed it is the object deck that is run followed by the data cards. The data cards, prior to the execution of this program, are sorted by house number with street name. That is, the street names in alphabetical order and within each street name group, the house numbers are sequential -- lowest number first. The last card in the deck of data cards should contain all Z's. This is a trailer card and will indicate the end of the data card file.

The first card is a code card and should be an O or an E. In order to get a complete lookup of addresses the program has to be run twice. Once with an O code card, then with an E or vice versa. The reason for this is explained in the Suggested Improvements paragraph.

To start a run, the object deck followed by an O or E card, the data deck, and a trailer card is loaded in the card reader and the Dictionary tape is mounted on Tape Drive 1. The printer and the card puncher should be turned on so the output can be written.

### Main Procedure

The data cards are read and the program tries to find a record in the tape with the same street name by reading the tape sequentially until a match occurs. Once there is a match on street name then the program checks to see if the house number on the cards falls within the range of addresses for that block. The record in the Dictionary also has a code of O and E. It is important that the data cards not only match on street name and fall within the address range, but that the code applies to the house number. That is, if the house number is odd, an O record only should lead to the ultimate match. To illustrate the errors that would occur if this were not provided, assume for a given street name on the Dictionary the records were:

<u>Code</u>	<u>Street Name</u>	<u>Address</u>	<u>Range</u>	<u>Tract #</u>	<u>Block #</u>
O	George St	01	09	06	101
E	George St	02	10	06	102

and the data card had the address: 6 George Street. The program would accept Tract 06, Block 101, since street name matches and 6 is within the 01-09 range. To prevent this, each data card is checked with a routine that determines if the house number is odd or even and the O or E, respectively, is put in a storage area (H code).

#### Final Procedure

When the trailer card of Z's is read all files are closed and the run is stopped.

#### Error Procedure

If the address on the data card cannot be found in the Dictionary an error message is written in the printed report. The house number and street name on the data card is written under the appropriate columns in the report. Under the column entitled, "Low Intersecting Street", the message, "Not on File" is written. The rest of the line is blank.

Since the present Dictionary format cannot give nearest block numbers or tract number when the house number is blank the lookup program bypasses any cards whose house number is blank.

#### Program Listing

The complete field description of the complaint code data card is listed in back. For the program as now written, the only fields needed are the following:

<u>Column</u>	<u>Contents</u>
17-20	House number
21-37	Street name

The format of the punched card output has been indicated in the Users' Guide.

The format of the printed report is selfevident since each column is headed with the title of its contents.

The format of the Dictionary is:

<u>Column</u>	<u>Contents</u>
1	Code
2-17	Main street
25-41	Low intersecting street
43-59	High intersecting street
61-65	Tract number
67-71	Facing tract number
73-76	Low address
78-81	High address

#### Suggested Improvements

Under the present system the Lookup program must be run twice to get the desired information. This is because the Dictionary is on tape and therefore must be read sequentially. (This is, incidentally, very time consuming, thereby costing more in machine time, console operator fee and delay time. Since the file is in alphabetic order by street name, if the first street name on the data card was Post Street, every record on the Dictionary prior to Post Street would have to be read before reading Post Street.)

To illustrate why Lookup must be run twice, assume the following is a section of the Dictionary:

	<u>Code</u>	<u>Street Name</u>	<u>Low Address</u>	<u>High Address</u>
(1)	O	Crown St	01	11
(2)	E	Crown St	02	08
(3)	O	Crown St	13	25
(4)	E	Crown St	10	16
(5)	O	Crown St	27	33
(6)	E	Crown St	18	36

and that the address on the data cards will be read in as follows:

(1)	6	Crown St
(2)	9	Crown St
(3)	12	Crown St
(4)	18	Crown St
(5)	21	Crown St

The tape is read until the street names match. Data card 1 is even so it must match an E record and fall in the address range. Record 1 is read and by passed. Record 2 is the proper match and information is retrieved. Data card 2 is odd, so record 2 is bypassed and record 3 is read. However, the address range is too high. The correct match is in record 1, but that record was already read and bypassed. It cannot be accessed again in this run. Even if odd and even records were linked together and accessed jointly, the problem would not be solved. Further processing of the example will illustrate this.

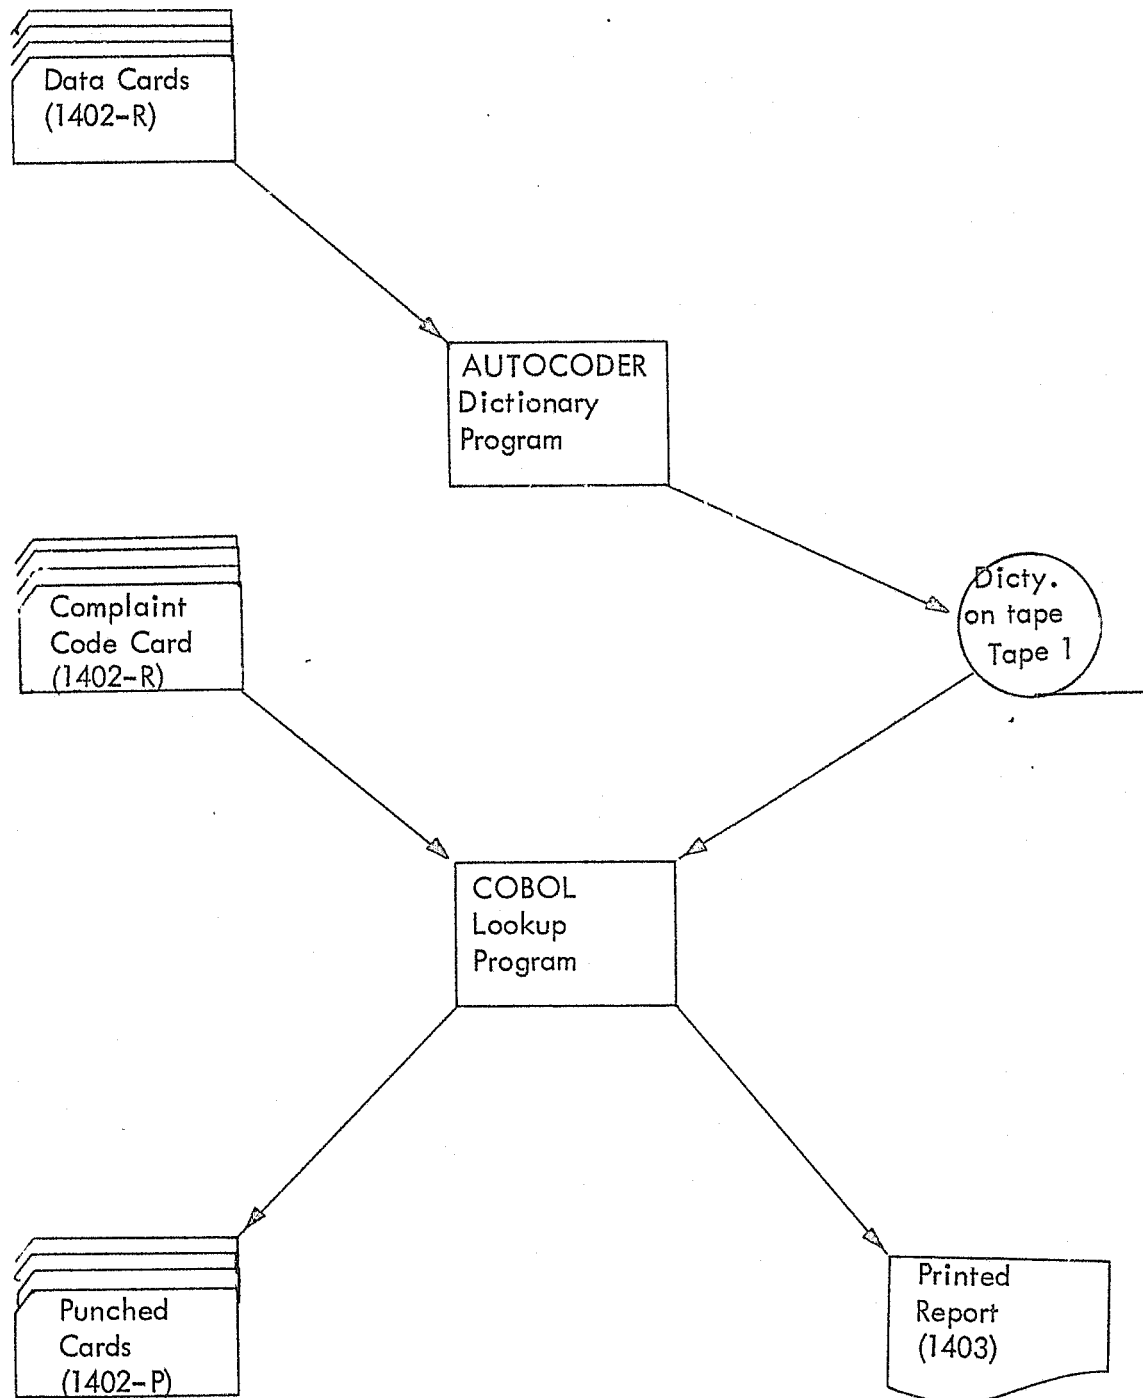

No match is found for data card 2. Data card 3 is read. It's even so record 3 is bypassed and record 4 is read. Record 4 matches and the desired information is retrieved. Data card 4 is read. Record 4 is not a match on address range, bypass it and read record 5. Record 5 is odd, bypass it and read record 6. This is a match. Data card 5 is odd, record 6 not a match. Even if odd-even records were linked the address range is not the same distance for each and in the last case data card 5 would still not be matched: Record 1 and 2 are linked so data cards 1 and 2 matched. Records 3 and 4 are linked, data card 3 is matched. Data card 4 not in that linked record so read records 5 and 6. Match data card 4 with record 6. Data card 5 doesn't match either record 4 or 5, its match is in record 3. So, even with linking, the problem is unsolved. Using tape, lookup must be run twice.

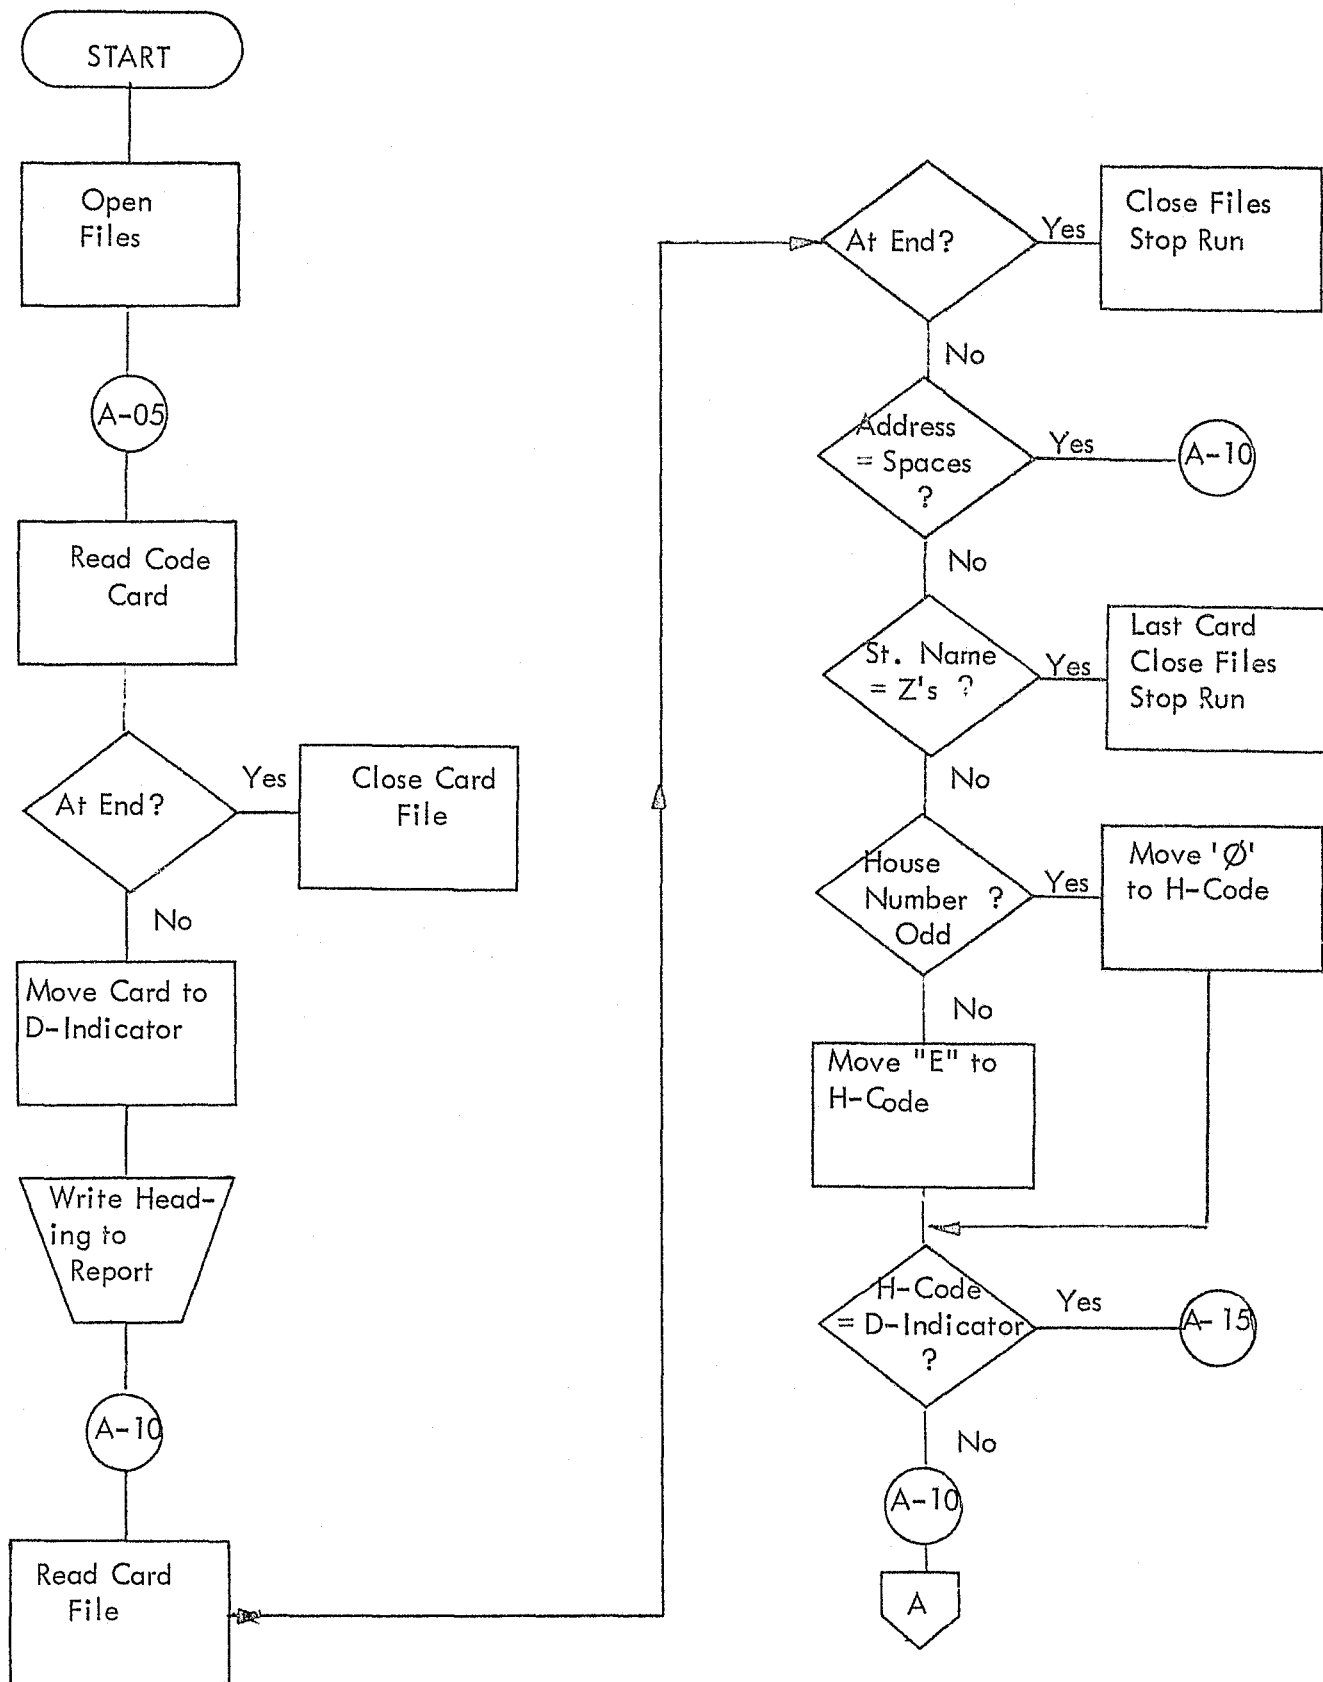

If the dictionary were on disk, organized sequentially as before, a given street name could be accessed immediately since disk permits random access. Post St can be retrieved immediately without reading street names A-P. An odd address whose record precedes the even address just processed can get the record. With a full scale dictionary of a city the tape dictionary would not be practical.
