ABOUT THE TECHNOLOGY ASSESSMENT PROGRAM

The Technology Assessment Program is sponsored by the Office of Development, Testing, and Dissemination of the National Institute of Justice (NIJ), U.S. Department of Justice. The program responds to the mandate of the Justice System Improvement Act of 1979, which created NIJ and directed it to encourage research and development to improve the criminal justice system and to disseminate the results to Federal, State, and local agencies.

The Technology Assessment Program is an applied research effort that determines the technological needs of justice system agencies, sets minimum performance standards for specific devices, tests commercially available equipment against those standards, and disseminates the standards and the test results to criminal justice agencies nationwide and internationally.

The program operates through:

The *Technology Assessment Program Advisory Council* (TAPAC) consisting of nationally recognized criminal justice practitioners from Federal, State, and local agencies, which assesses technological needs and sets priorities for research programs and items to be evaluated and tested.

The *Law Enforcement Standards Laboratory* (LESL) at the National Bureau of Standards, which develops voluntary national performance standards for compliance testing to ensure that individual items of equipment are suitable for use by criminal justice agencies. The standards are based upon laboratory testing and evaluation of representative samples of each item of equipment to determine the key attributes, develop test methods, and establish minimum performance requirements for each essential attribute. In addition to the highly technical standards, LESL also produces user guides that explain in nontechnical terms the capabilities of available equipment.

The *Technology Assessment Program Information Center* (TAPIC) operated by the International Association of Chiefs of Police (IACP), which supervises a national compliance testing program conducted by independent agencies. The standards developed by LESL serve as performance benchmarks against which commercial equipment is measured. The facilities, personnel, and testing capabilities of the independent laboratories are evaluated by LESL prior to testing each item of equipment, and LESL helps the Information Center staff review and analyze data. Test results are published in Consumer Product Reports designed to help justice system procurement officials make informed purchasing decisions.

Publications issued by the National Institute of Justice, including those of the Technology Assessment Program, are available from the National Criminal Justice Reference Service (NCJRS), which serves as a central information and reference source for the Nation's criminal justice community. For information, on how to order or to register with NCJRS, write to the National Institute of Justice, National Criminal Justice Reference Service, Washington, DC 20531.

ACKNOWLEDGMENTS

This standard was formulated by the Law Enforcement Standards Laboratory of the National Bureau of Standards under the direction of Marshall J. Treado, Program Manager for Communications Systems, and Lawrence K. Eliason, Chief of LESL. NBS Electromagnetic Fields Division staff members responsible for the preparation of the standard were Harold E. Taggart and John F. Shafer. The preparation of this standard was sponsored by the National Institute of Justice, Lester D. Shubin, Standards Program Manager. The standard has been reviewed and approved by the Technology Assessment Program Advisory Council and adopted by the International Association of Chiefs of Police (IACP) as an IACP standard.

FOREWORD

This document, NIJ Standard-0222.00, Surveillance Receiver/Recorders, is an equipment standard developed by the Law Enforcement Standards Laboratory of the National Bureau of Standards. It is produced as part of the Technology Assessment Program of the National Institute of Justice. A brief description of the program appears on the inside front cover.

This standard is a technical document that specifies performance and other requirements equipment should meet to satisfy the needs of criminal justice agencies for high quality service. Purchasers can use the test methods described in this standard themselves to determine whether a particular piece of equipment meets the essential requirements, or they may have the tests conducted on their behalf by a qualified testing laboratory. Procurement officials may also refer to this standard in their purchasing documents and require that equipment offered for purchase meet the requirements. Compliance with the requirements of the standard may be attested to by an independent laboratory or guaranteed by the vendor.

Because this NIJ standard is designed as a procurement aid, it is necessarily highly technical. For those who seek general guidance concerning the selection and application of law enforcement equipment, user guides have also been published. The guides explain in nontechnical language how to select equipment capable of the performance required by an agency.

NIJ standards are subjected to continuing review. Technical comments and recommended revisions are welcome. Please send suggestions to the Program Manager for Standards, National Institute of Justice, U.S. Department of Justice, Washington, DC 20531.

Before citing this or any other NIJ standard in a contract document, users should verify that the most recent edition of the standard is used. Write to: Chief, Law Enforcement Standards Laboratory, National Bureau of Standards, Washington, DC 20234.

1. PURPOSE

The purpose of this document is to establish performance requirements and methods of test for one type of receiving/recording system used in surveillance work. The equipment involved in these systems typically includes frequency modulated (FM) receivers, cassette recorders, and their associated antennas and power sources. The type addressed in this standard utilizes a 4.76 cm/s (1-7/8 in/s) Philips-type cassette [1]¹. A block diagram of a typical system is shown in figure 1.

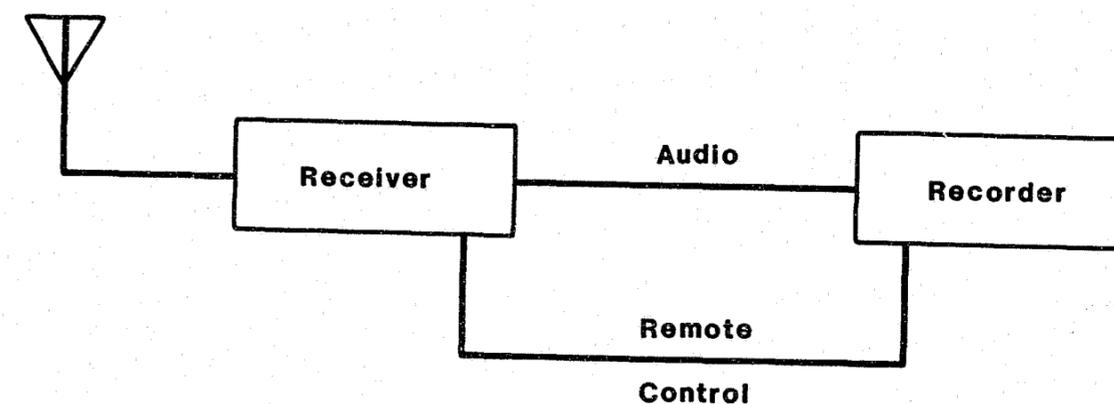

FIGURE 1. Block diagram for a typical surveillance receiver/recorder system.

2. SCOPE

This standard applies to receivers that either do not have special subsystems such as selective signaling or voice privacy, or in which such subsystems are bypassed or disabled during testing. Two types of FM receivers are available. One type is a fixed-frequency receiver, which operates in the 25-1000 MHz band with a receiver channel spacing of either 20, 25, or 30 kHz and is crystal-controlled on a specific carrier frequency. The other is a selectable-frequency receiver, which operates in the 25-1000 MHz band with the same channel spacing and is frequency tunable.

3. DEFINITIONS

The principal terms used in this document are defined in this section. Additional definitions relating to law enforcement communications are given in LESP-RPT-0203.00, Technical Terms and Definitions Used with Law Enforcement Communication Equipment [2].

3.1 Adjacent-Channel Selectivity and Desensitization

The ability of a receiver to discriminate against a signal at the frequency of an adjacent channel, either 20, 25 or 30 kHz away.

¹ Numbers in brackets refer to references in appendix A.

3.2 Audio Distortion

Nonlinear distortion in which the relative magnitude of different frequency components of a signal waveform are changed on either a phase or amplitude basis.

3.3 Audio Hum and Noise Power

The average audiofrequency power dissipated in a load across the output terminals of an unscelched receiver having no radiofrequency (rf) signal input.

3.4 Audio Noise Output Power

The average audiofrequency power dissipated in a load across the output terminals of an unscelched receiver having no rf signal input.

3.5 Audio Output Power

The audiofrequency power dissipated in a load across the receiver output terminals of an unscelched receiver having a modulated rf signal input.

3.6 Audio Response of a Receiver

The variation in the output of a receiver as a function of frequency within a specific audiofrequency bandwidth.

3.7 Fast Forward Mode

A tape transport operating mode in which the tape moves at high speed in the same direction used for recording.

3.8 Frequency Deviation

In frequency modulation, the difference between the instantaneous frequency of the modulated carrier and the unmodulated carrier frequency.

3.9 Intermodulation Attenuation

The ratio, expressed in decibels (dB), of (1) the level of specified signals that produces an *intermodulation response*² under specified conditions to (2) the receiver's *SINAD sensitivity*.

3.10 Intermodulation Response

The response resulting from the mixing of two or more frequencies, in the nonlinear elements of a receiver, in which a resulting frequency is generated that falls within the range of frequencies passed by the receiver.

3.11 Memory Retention

The ability of a scanning receiver to remain tuned to its manually selected channel when the ac power source is momentarily interrupted.

3.12 Noise Quieting

The reduction of audio noise output caused by the presence of an rf signal.

3.13 Nominal Value

The numerical value of a device characteristic as specified by the manufacturer.

² Italicized phrases in the Definitions section are also defined.

3.14 Playback Mode

A tape transport operating mode in which the tape passes over the playback head in the same direction as in the *record mode*, and recorded signals are sensed and amplified to drive the speaker.

3.15 Rated System Deviation

The maximum carrier *frequency deviation* permitted by the Federal Communications Commission (FCC). For law enforcement communications systems, it is ± 5 kHz.

3.16 Receiver Attack Time

The time required for the receiver to produce a specified *audio output power* level upon application of a specified rf input signal, when the squelch control is in the *threshold squelch position*.

3.17 Record Mode

A tape transport operating mode in which the tape passes over the erase head, where any previously recorded signals are erased, then passes over the record head where new signals are transferred to the tape.

3.18 Rewind Mode

A tape transport operating mode in which the tape is returned to its initial position at high speed.

3.19 Selectivity

The extent to which a receiver is capable of differentiating between the desired signal and signals at other frequencies.

3.20 SINAD Ratio

The ratio, expressed in decibels, of (1) signal plus noise plus distortion to (2) noise plus distortion produced at the output of a receiver; from *SINAD Signal Noise And Distortion Ratio*.

3.21 SINAD Sensitivity

The minimum modulated rf signal input level required to produce a specified *SINAD ratio* at a specified *audio output power* level.

3.22 Spurious Response

The output of a receiver caused by a signal at a frequency other than that to which the receiver is tuned.

3.23 Squelch

A circuit function for preventing a receiver from producing *audio output power* in the absence of an rf input signal.

3.24 Squelch Block

A squelched condition resulting from excessive *frequency deviation* due to the presence of a specified rf input signal.

3.25 Standby Mode

The condition of a receiver when it is energized but not receiving.

3.26 Threshold Squelch Position

The adjustment of a squelch control, starting from the maximum unscelched position, that first reduces the *audio noise output power* by a specified amount.

3.27 Threshold Squelch Sensitivity

The minimum standard modulated rf signal input level required to unsquelch a receiver when the squelch control is in the *threshold squelch position*.

3.28 Tight Squelch Sensitivity

The minimum standard modulated rf signal input level required to unsquelch a receiver when the squelch control is in the maximum squelch position.

3.29 Usable Bandwidth

The *frequency deviation* of an input signal that is 6 dB above the 12-dB *SINAD sensitivity* voltage and which produces a 12-dB *SINAD ratio*.

4. REQUIREMENTS

4.1 Minimum Performance

The performance of the surveillance receiver/recorder shall meet or exceed the requirement for each characteristic listed in table 1. The performance requirements listed in table 1 meet those given in the Rules and Regulations published by the FCC [3].

4.2 User Information

4.2.1 Receivers

A nominal value for each receiver characteristic listed in table 1 shall be included in the information supplied to the purchaser by the manufacturer or distributor. In addition, the distributor shall provide:

- The range of temperatures within which the receiver is designed to be operated.
- The receiver operating frequencies or range of frequencies.
- Nominal values for receiver audio output impedance, standard supply voltage, and the current drain of the receiver in both the receive and standby modes.

4.2.2 Recorders

The nominal value for each recorder characteristic shall be included in the information supplied to the purchaser by the manufacturer or distributor. These characteristics shall include:

- The size and number of batteries required for operation.
- The audio input impedance and audio output impedance of the recorder.
- The remote control switching requirements.
- The current drain of the recorder in both the record and playback modes.

4.3 Receiver SINAD Sensitivity

When measured in accordance with section 5.3, the SINAD sensitivity of the receiver shall be 0.5 μV (item A, table 1) or less at a SINAD ratio of 12 dB and an audio output power of at least 250 mW. When the standard supply voltage is varied +10 percent and -20 percent, the SINAD sensitivity shall be 0.7 μV or less.

4.4 Receiver Selectivity Characteristics

The selectivity characteristics of usable bandwidth, adjacent-channel selectivity and desensitization, spurious response attenuation, and intermodulation attenuation shall be measured in accordance with section 5.4.

4.4.1 Usable Bandwidth

The usable bandwidth of the receiver shall be at least 5 kHz for an applied rf signal 6 dB above the measured 12-dB SINAD sensitivity value.

TABLE 1. Minimum performance requirements for FM receivers and recorders used in surveillance systems.

Receiver characteristic	Minimum requirement 25-1000 MHz frequency band	Test method section No.
Sensitivity Characteristics		
A. SINAD Sensitivity	0.5 μV	5.3
B. SINAD Sensitivity Variance (Supply Voltage Varied +10% and -20%)	0.7 μV	5.3
Selectivity Characteristics		
C. Usable Bandwidth	5 kHz	5.4.1
D. Adjacent-Channel Selectivity and Desensitization	60 dB	5.4.2
E. Spurious Response Attenuation	60 dB	5.4.3
F. Intermodulation Attenuation	60 dB	5.4.4
Squelch Characteristics		
G. Threshold Squelch Sensitivity	0.4 μV	5.5.1
H. Tight Squelch Sensitivity	4.0 μV	5.5.1
I. Threshold Squelch Sensitivity Variance (Supply Voltage Varied +10% and -20%)	0.6 μV	5.5.1
J. Squelch Block	± 5 kHz	5.5.2
K. Receiver Attack Time	150 ms	5.5.3
Audiofrequency Characteristics		
M. Audio Output Power (Loudspeaker)	500 mW	5.6.1
N. Audio Output Power (Earphones)	3-12 mW	5.6.1
O. Audio Output Power Variance (Supply Voltage Varied +10% and -20%)	3 dB	5.6.1
P. Audio Distortion	10%	5.6.2
Q. Audio Response (Loudspeaker)	-10,+2 dB	5.6.3
R. Audio Response (Earphones)	-10,+2 dB	5.6.3
S. Audio Hum and Noise (Unsquelched)	40 dB	5.6.4
T. Audio Hum and Noise (Squelched)	50 dB	5.6.4
Temperature Stability		
U. SINAD Sensitivity	6 dB	5.7
V. Usable Bandwidth	20%	5.7
W. Adjacent Channel Selectivity and Desensitization	12 dB	5.7
X. Tight Squelch Sensitivity	6 dB	5.7
Y. Threshold Squelch Sensitivity	6 dB	5.7
Z. Audio Output Power	6 dB	5.7
AA. Audio Hum and Noise	10 dB	5.7
AB. Audio Distortion	18%	5.7
Recorder Characteristics		
AC. Fast Forward Time	90 s	5.9.1
AD. Rewind Time	90 s	5.9.1
AE. Tape Speed Tolerance	$\pm 2\%$	5.9.2
Receiver/Recorder Characteristics		
AF. Receiver/Recorder System Audio Distortion	15%	5.10.1
AG. Receiver/Recorder System Audio Response	-11,+3 dB	5.10.2
AH. Battery Service Life	4 h	5.10.3

4.4.2 Adjacent-Channel Selectivity and Desensitization

The adjacent-channel selectivity and desensitization of the receiver shall be at least 60 dB for a degradation of an on-channel signal from 12-dB SINAD ratio to 6-dB SINAD ratio caused by the presence of an adjacent-channel signal.

4.4.3 Spurious Response Attenuation

The spurious response attenuation of the receiver shall be at least 60 dB as compared to the on-channel 20-dB noise quieting signal voltage for responses of the receiver between the lowest intermediate frequency of the receiver and 1000 MHz.

4.4.4 Intermodulation Attenuation

The intermodulation attenuation of the receiver shall be at least 60 dB for a degradation of an on-channel signal from 12-dB SINAD ratio to 6-dB SINAD ratio by two signals at least 54 dB above a microvolt ($\text{dB}\mu\text{V}$) at one- and two-channel spacings away, respectively, from the receiver frequency, both signals being at frequencies either above or below the on-channel signal.

4.5 Receiver Squelch Characteristics

The squelch characteristics of sensitivity, block, and receiver attack time shall be measured in accordance with section 5.5.

4.5.1 Squelch Sensitivity

The threshold squelch sensitivity of the receiver shall be $0.4 \mu\text{V}$ or less. The tight squelch sensitivity shall be $4.0 \mu\text{V}$ or less. When the standard supply voltage is varied +10 percent and -20 percent, the threshold squelch sensitivity shall be $0.6 \mu\text{V}$ or less.

4.5.2 Squelch Block

The receiver shall not squelch for modulation frequencies of 0.3 to 3 kHz when the squelch control is adjusted to the maximum squelch position and the frequency deviation of the input signal is ± 5 kHz or less.

4.5.3 Receiver Attack Time

The time for the receiver to produce 90 percent of the required audio output, 450 mW, shall be 150 ms or less.

4.6 Receiver Audio Characteristics

The audio characteristics of output power, distortion, response, and hum and noise shall be measured in accordance with section 5.6.

4.6.1 Audio Output Power

The audio output power of the receiver shall be at least 500 mW if a loudspeaker is used at the receiver output, and at least 3 mW, but not greater than 12 mW, if earphones are used. When the standard supply voltage is varied +10 percent and -20 percent, the audio output power shall not be reduced more than 3 dB below 500 mW.

4.6.2 Audio Distortion

The audio distortion at audio powers of 500 mW (loudspeaker) and 3-12 mW (earphones) shall be less than 10 percent for an rf input signal with standard audio test modulation.

4.6.3 Audio Response

The audio response of the receiver, when used with either a loudspeaker or earphones, shall be within -10, +2 dB of an ideal 6 dB per octave de-emphasis curve with constant frequency deviation at frequencies between 0.3 and 3 kHz.

4.6.4 Audio Hum and Noise

The audio hum and noise output power from the receiver in the unquieted condition shall be at least 40 dB below, and in the maximum quieted condition shall be at least 50 dB below, an audio output power of 500 mW.

4.7 Receiver Performance at Temperature Extremes

The ability of the receiver to operate in temperature extremes shall be determined using the test method described in section 5.7.

Low temperature tests shall be conducted at -10°C (14°F) or the lowest temperature at which the manufacturer states that the receiver will operate properly, whichever is lower, and high temperature tests shall be conducted at $+60^\circ\text{C}$ (140°F) or the highest temperature at which the manufacturer states that the unit will operate properly, whichever is higher (sec. 4.2.1).

When the receiver is operated at low and high temperatures, as defined above, its performance shall not vary, with respect to the appropriate values in table 1 (items A through T), more than items U through AA for the characteristics listed. In addition, the receiver audio distortion at an audio output power of 500 mW shall be less than 18 percent for an rf signal with standard modulation.

4.8 Receiver Memory Retention

When tested in accordance with section 5.8, the receiver shall remain tuned to its operating frequency when the rf signal to the receiver input is temporarily interrupted during operation. The receiver shall also remain tuned to its operating frequency when the power is interrupted during operation.

4.9 Recorder Performance

The cassette recorder characteristics of fast forward and rewind, tape speed and anti-erase feature shall be measured in accordance with section 5.9.

4.9.1 Type of Cassette and Tape

The recorder system shall employ a Philips-type cassette [1,4] and magnetic tapes with ferric oxide coatings.

Note: Tapes which have other metallic coatings do not perform as well as ferric oxide on cassette recorders intended for ferric oxide tapes because of the higher bias requirements of these tapes.

4.9.2 Operating Modes and Controls

Each recorder shall have the following distinct operating modes: Record, Playback, Fast Forward, Rewind, and Stop. All controls essential to the operation of the recorder shall be plainly identified in English or universal symbols. The tape recorder shall have one external jack connector that allows the recorder to be started and stopped while in the record mode. The recorder shall also be equipped with a visual audio input indicator that corresponds to an acceptable range of input signals and a relative tape position counter. If the latter is digital, a reset capability should also be provided.

4.9.3 Fast Forward and Rewind

The time required to advance or rewind a 30-min length of tape shall not exceed 90 s.

4.9.4 Tape Speed

The recorder tape speed shall be within ± 2 percent of 4.76 cm/s (1-7/8 in/s).

4.9.5 Anti-Erase Feature

Each recorder shall be equipped with an anti-erase mechanism that prevents the record lever from being energized if either of the two breakout tabs or sliding plate covers on the cassette are removed or placed in the open position.

4.10 Receiver/Recorder System Performance

The receiver/recorder system characteristics of audio distortion, audio response, and battery service life shall be measured in accordance with section 5.10.

4.10.1 System Audio Distortion

The audio distortion of the receiver and recorder system shall not exceed 15 percent.

4.10.2 System Audio Response

The audio response of the receiver and recorder system shall be within -11 , $+3$ dB of an ideal 6 dB per octave de-emphasis curve at frequencies between 0.3 and 3.0 kHz.

4.10.3 Battery Service Life

The receiver/recorder battery service life shall be at least 4 h with a system audio distortion of 15 percent or less.

5. TEST METHODS

5.1 Standard Test Conditions

Allow all measurement equipment to warm up until the system has achieved sufficient stability to perform the measurement. Unless otherwise specified, perform all measurements under standard test conditions.

5.1.1 Standard Temperature

Standard ambient temperature shall be between 20°C (68°F) and 30°C (86°F).

5.1.2 Standard Supply Voltage (Receiver)

The standard supply voltage shall be the nominal voltage specified by the manufacturer (sec. 4.2). Tests shall be performed using either a battery of the type normally used in the equipment, an electronic dc supply, or 120-V ac at 60 Hz in the case of ac-powered equipment. If an electronic power supply is used, it shall be adjusted to within 1 percent of the voltage required.

5.1.3 Standard Test Frequency

The standard test frequency shall be one of the receiver operating frequencies. When testing frequency-tunable receivers, select a single frequency within the operating range of the receiver and conduct all tests at the selected frequency.

5.1.4 Standard Audio Test Modulation

Audio test modulation shall be a 1-kHz signal (from a source with distortion less than 1 percent) at the level required to produce 60 percent of rated system deviation (i.e., ± 3 kHz).

5.1.5 Standard Squelch Adjustment

The squelch control shall be adjusted to the maximum unsquelched position for all receiver measurements except where otherwise noted.

5.2 Test Equipment

The test equipment discussed in this section is limited to that equipment which is most critical in making the measurements discussed in this standard. All other test equipment shall be of comparable quality.

5.2.1 FM Signal Generator

The FM signal generator shall have a frequency range from 25–1000 MHz, a 50-ohm output impedance, a maximum standing-wave ratio of 1.2, and a calibrated variable output level accurate to ± 2 dB when terminated in a 50-ohm load. The generator should include a digital frequency counter having an uncertainty no greater than 1 ppm and a deviation monitor or calibrated control for determining the peak frequency deviation with an uncertainty of no greater than 5 percent. If an integral frequency counter is not included, a separate frequency counter having the required accuracy shall be provided.

5.2.2 CW Signal Generator

The CW signal generator shall have the characteristics described in section 5.2.1, except that the FM capability is not required.

5.2.3 Standard RF Input Load (Receiver)

The standard rf input load shall consist of a shielded 50-ohm resistor whose standing wave ratio is less than 1.05.

5.2.4 Standard Audio Output Load (Receiver)

The standard audio output load shall be a resistor having a resistance equal to the nominal output impedance of the receiver and a power rating equal to or exceeding the nominal audio output power of the receiver. A filter network shall not be used between the audio output terminals and the audio output load. If an external monitor is used, it shall have an input impedance of at least 10,000 ohms.

5.2.5 Audiofrequency Voltmeter

The audiofrequency voltmeter shall measure rms voltage rather than average or peak voltage. Its measurement uncertainty shall be 1 percent or less.

5.2.6 Signal Combiner

The signal combiner shall have an amplitude imbalance no greater than 0.2 dB, its standing wave ratio shall be no greater than 1.3, and the isolation between input terminals shall be a minimum of 30 dB. A variety of multiport devices may be used as signal combiners, including power dividers, directional couplers, and hybrid junctions.

5.2.7 Environmental Chamber

The environmental chamber shall produce air temperatures from -30 to 60°C (-22 to 140°F). The test item shall be shielded from air currents blowing directly from heating or cooling elements in the chamber. The temperature of the test item shall be measured with a thermometer separate from the sensor used to control the chamber air temperature.

5.2.8 Distortion Analyzer

The distortion analyzer shall have a required input level of between 1- and 5-V rms, an input impedance of at least 50,000 ohms shunted by less than 100 pF, and an accuracy of at least ± 1 dB for the SINAD measurements. It shall have the capability to measure both audio distortion and the voltage of audio signals to within ± 3 percent. The analyzer shall incorporate a 1000 Hz band elimination filter for the audio distortion measurements.

5.3 Receiver SINAD Sensitivity Test

Connect the receiver and test equipment as shown in figure 2. Set the squelch control to the standard squelch adjustment. Adjust the FM signal generator to the standard test frequency with standard audio test modulation. Set the generator for a 1-mV output and the receiver volume control for a loudspeaker audio output power of 500 mW. Do not readjust the volume control for the remainder of the measurement. Decrease the output level of the generator until the SINAD ratio of the receiver is 12 dB, as determined with the distortion analyzer. Measure the audio output power to make certain it is at least 250 mW and record the generator output voltage for convenience in resetting to a 12-dB SINAD ratio, as required by

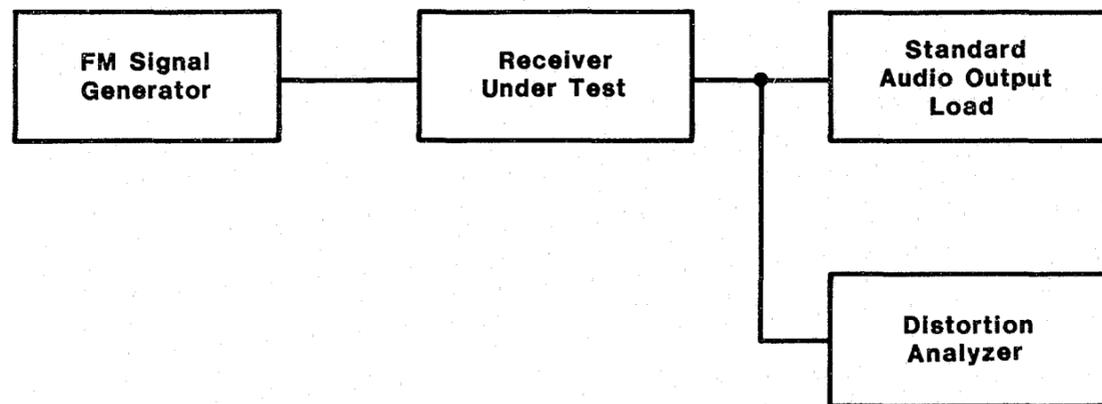

FIGURE 2. Block diagram for SINAD sensitivity, usable bandwidth, squelch sensitivity, squelch block, audio distortion, and memory retention measurement.

some of the following tests. Repeat the above using +10 percent and -20 percent changes in standard supply voltage.

5.4 Receiver Selectivity Tests

5.4.1 Usable Bandwidth Test

Connect the receiver and test equipment as shown in figure 2. Adjust the receiver and FM generator in accordance with section 5.3 until a 12-dB SINAD ratio is reached. With the generator still set for standard audio test modulation, increase the generator rf output by 6 dB. Adjust the frequency of the generator above the test frequency until the 12-dB SINAD signal ratio is again obtained. Record the generator frequency. Repeat this measurement by adjusting the generator frequency below the test frequency and record the generator frequency. The smaller displacement from the test frequency plus 3 kHz (standard audio test modulation) is the receiver usable bandwidth.

5.4.2 Adjacent-Channel Selectivity and Desensitization Test

Connect the receiver and test equipment as shown in figure 3. With the output of generator No. 2 set to zero, adjust the receiver and signal generator No. 1 in accordance with section 5.3 until a 12-dB SINAD ratio is reached. Adjust signal generator No. 2 for 3 kHz with a modulation frequency of 400 Hz, and set it to a frequency corresponding to the center of the next higher adjacent channel. Then adjust the output of signal generator No. 2 to produce a 6-dB SINAD ratio with both signals present. The ratio, in decibels, of the output voltage of signal generator No. 2 to that of signal generator No. 1 is the adjacent-channel selectivity for the upper channel. Repeat the above procedure for the next lower adjacent channel. The smaller of the two ratios is the value sought.

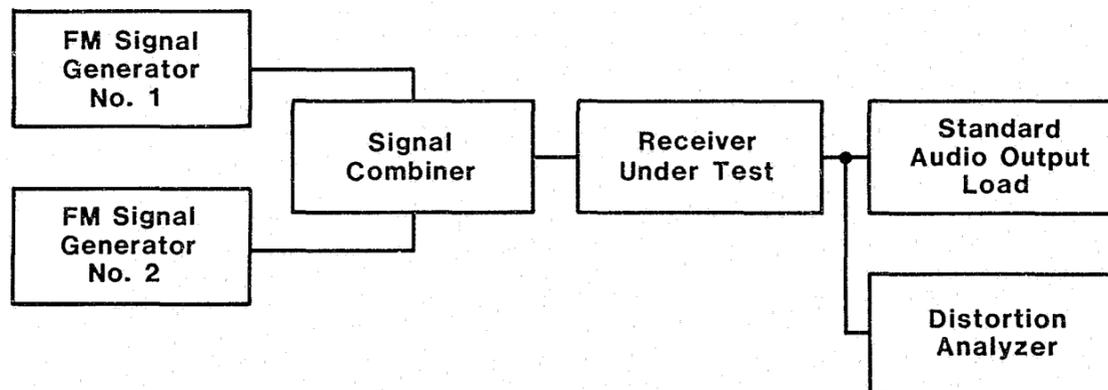

FIGURE 3. Block diagram for adjacent-channel selectivity and desensitization measurement.

5.4.3 Spurious Response Attenuation Test

Connect the receiver and test equipment as shown in figure 4. Adjust the unmodulated (CW) signal generator to the standard test frequency. With the generator adjusted for zero output, adjust the receiver volume control to produce 125 mW. This output power is entirely noise power. Do not readjust the volume control for the remainder of the measurement. Increase the output of the generator until the audio noise output power of the receiver is decreased by 20 dB, i.e., 20 dB of noise quieting. Note the generator output in dB μ V at this frequency. Then increase the output of the generator to approximately 0.1 V, and slowly vary the generator frequency continuously from just below the lowest intermediate frequency of the receiver to 1000 MHz. Note each frequency that produces a response as indicated by noise quieting in the receiver's audio output. Ignore harmonic frequencies of the generator that fall within the channel to which the receiver is tuned. For each response, adjust the generator output to produce 20 dB of noise quieting. Record the generator output in dB μ V. The generator output at the spurious response frequency minus the generator output at the standard test frequency is the spurious response attenuation. Repeat for all spurious responses. The smallest attenuation is the value sought.

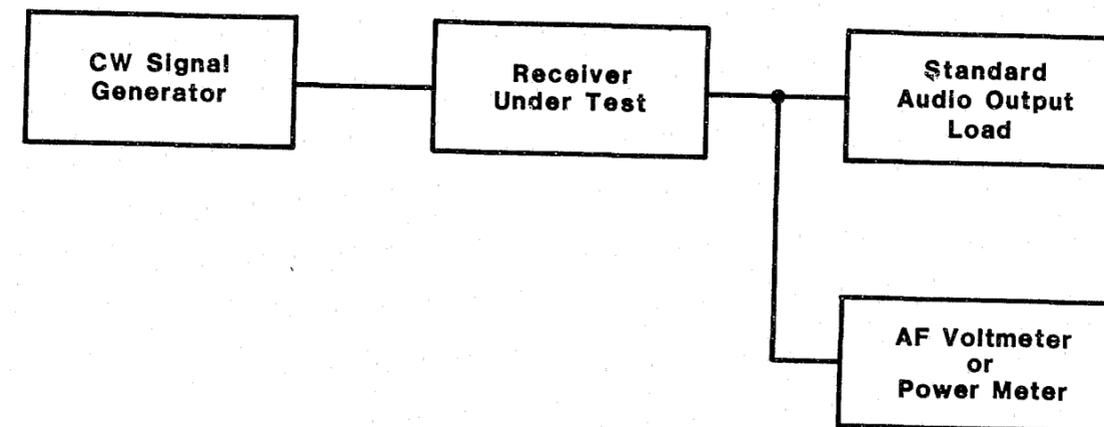

FIGURE 4. Block diagram for spurious response attenuation measurement.

5.4.4 Intermodulation Attenuation Test

Connect the receiver and test equipment as shown in figure 5. With the output levels of signal generators No. 2 and No. 3 set to zero, adjust the receiver and FM signal generator No. 1 in accordance with section 5.3 until a 12-dB SINAD ratio is reached. Adjust unmodulated generator No. 2 to the center frequency of the next higher adjacent channel (see sec. 2). Adjust generator No. 3 for 3-kHz frequency deviation at 400 Hz, and set it to the center frequency of the second higher adjacent channel, i.e., two channels above the standard test frequency. Then adjust the output levels of generator Nos. 2 and 3 to produce a 6-dB SINAD ratio with all three signals present. Maintain generator Nos. 2 and 3 at equal output voltage throughout the measurement. Slightly adjust the frequency of generator No. 3 to obtain the 6-dB SINAD ratio with the minimum signal levels from generator Nos. 2 and 3 unchanged. The ratio, in decibels, of the output voltage of generator No. 2 (or No. 3) to that of generator No. 1 is the intermodulation attenuation for the upper channels. Repeat the above procedures for the lower two adjacent channels, with generator No. 3 set to the lowest channel. The smaller of the two ratios is the value sought.

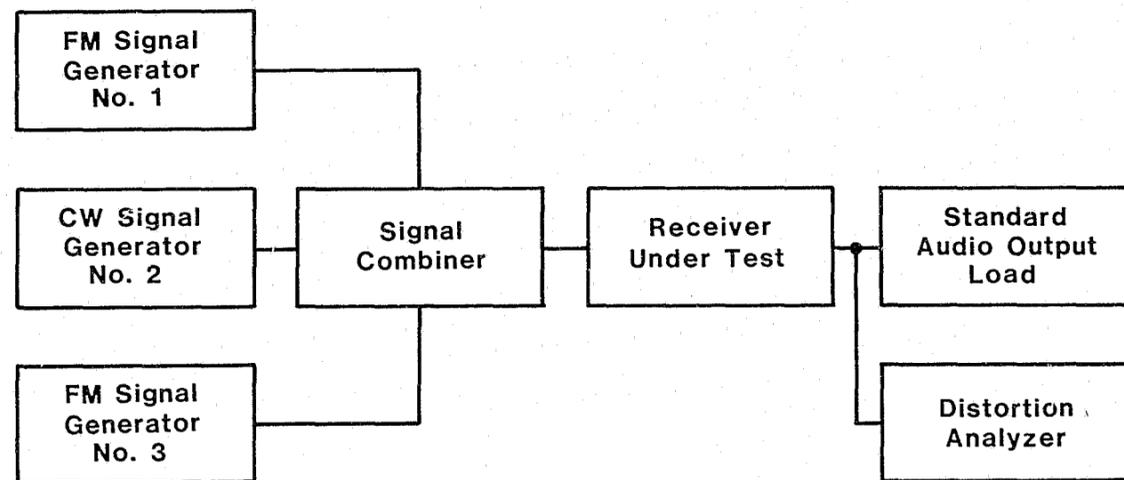

FIGURE 5. Block diagram for intermodulation attenuation measurement.

5.5 Receiver Squelch Tests

5.5.1 Squelch Sensitivity Tests

Connect the receiver and test equipment as shown in figure 2. Adjust the receiver and FM signal generator in accordance with section 5.3 until a 12-dB SINAD ratio is reached. Set the output level of the generator to zero, and measure the audio noise output power. Slowly adjust the squelch control until the audio noise output power drops abruptly (40 dB or more). Do not adjust the squelch control any further. This is the threshold squelch position. Increase the output level of the signal generator until the measured audio output power is within 10 dB of an audio output power of 500 mW. The signal generator output voltage is the value for threshold squelch sensitivity. Repeat using +10 percent and -20 percent standard supply voltages.

Repeat the above procedure with the squelch control in the maximum squelch position. The resultant signal generator output voltage is the value for tight squelch sensitivity.

5.5.2 Squelch Block Test

Connect the receiver and test equipment as shown in figure 2. Adjust the receiver and FM signal generator in accordance with section 5.3 until a 12-dB SINAD ratio is reached. Set the output level of the signal generator to zero, and measure the audio noise output power. Then set the squelch control to the maximum squelch position. Adjust the output level of the generator to 12 dB above the measured value of the receiver's tight squelch sensitivity voltage as determined in 5.5.1. Then increase the frequency deviation of the generator until the audio output power drops abruptly (40 dB or more). Repeat the above procedure with modulation frequencies of 0.3, 0.5, 2.5, and 3 kHz. The frequency deviations of signal generator modulation are the values sought.

5.5.3 Receiver Attack Time Test

Connect the equipment as shown in figure 6a. Open and close the SPST switch to trigger the oscilloscope trace. Connect the dc output of the coaxial diode detector to the vertical input of the oscilloscope and adjust the horizontal centering controls so that the start of the detector output begins at the left graticule of the oscilloscope screen. Do not adjust the oscilloscope trigger or centering controls any further.

Connect the transceiver receiver and test equipment as shown in figure 6b. With the SPST switch closed, adjust the FM signal generator in accordance with section 5.3 until a 12-dB SINAD ratio is reached. Set the signal generator to zero and measure the audio noise output power. Slowly adjust the squelch control until the audio output power drops abruptly (40 dB or more). Do not adjust the squelch any further. Adjust the generator output level to 12 dB above the measured value of the receiver threshold squelch sensitivity voltage. With the oscilloscope on recurrent sweep, adjust the oscilloscope vertical controls for

full-scale deflection. Do not adjust the trigger. Return the oscilloscope to external trigger and open and then close the SPST switch and photograph the trace. The time required for the sweep to travel from the left side of the oscilloscope graticule until the audio output power level reaches 450 mW is the value of receiver attack time.

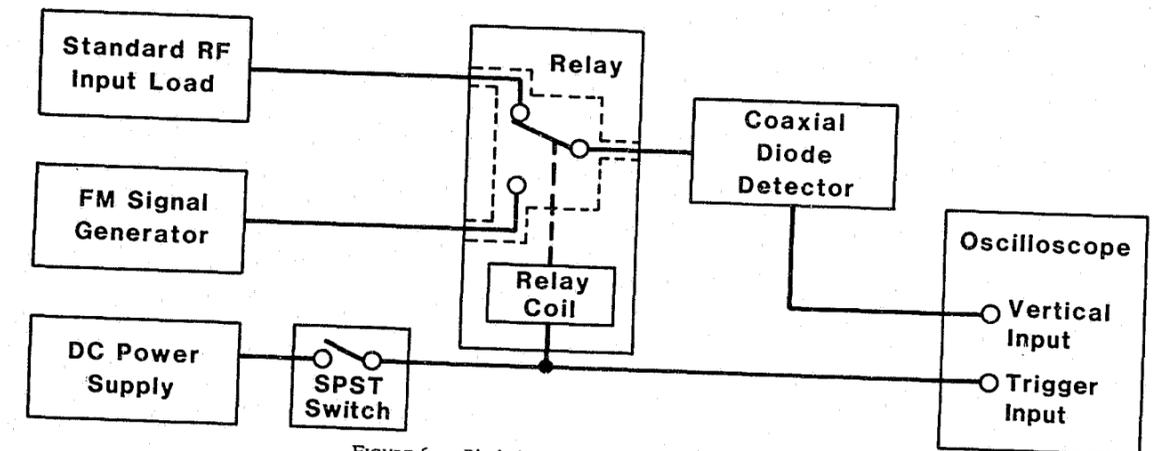

FIGURE 6a. Block diagram for setting oscilloscope trigger.

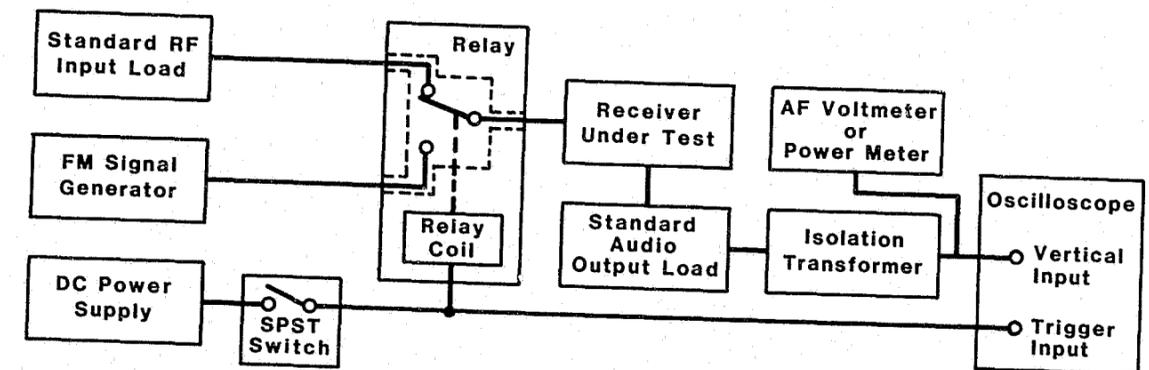

FIGURE 6b. Block diagram for receiver attack time measurement.

5.6 Receiver Audio Tests

5.6.1 Audio Output Power Test

Connect the receiver and test equipment as shown in figure 7. Modulate the FM signal generator with standard audio test modulation and set it to the standard test frequency. With the signal generator adjusted for 1-mV output, set the receiver volume control to the maximum position, and measure the audio output power. Repeat using +10 percent and -20 percent standard supply voltages (both ac and dc).

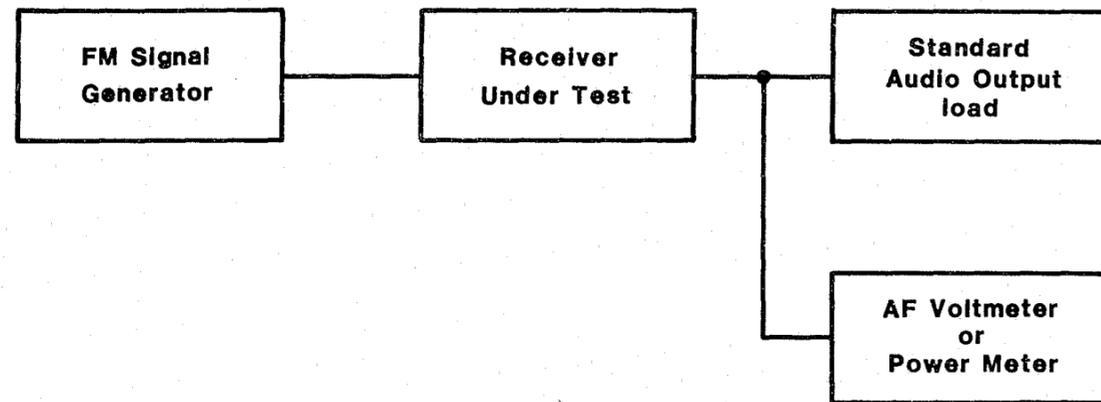

FIGURE 7. Block diagram for audio output power, audio response, and audio hum and noise measurements.

5.6.2 Audio Distortion Test

Connect the receiver and test equipment as shown in figure 2. Modulate the FM signal generator with standard audio test modulation and set it to the standard test frequency. With the signal generator adjusted for 1-mV output, adjust the receiver volume control for an audio output power of 500 mW and measure the audio distortion. Repeat at an audio output power of 3–12 mW for those receivers equipped with earphones.

5.6.3 Audio Response Test

Connect the receiver and test equipment as shown in figure 7. Modulate the FM signal generator with standard audio test modulation and set it to the standard test frequency. With the signal generator adjusted for 1-mV output, adjust the receiver volume control to an audio output power of 250 mW. Do not readjust the volume control for the remainder of the measurement. Reduce the generator frequency deviation to 1 kHz and measure the audio output power. Repeat for modulating frequencies of 0.3, 0.5, 2, and 3 kHz. Calculate the ratio, in decibels, of each of these latter power levels to the output power at 1 kHz.

5.6.4 Audio Hum and Noise Tests

Connect the receiver and test equipment as shown in figure 7. Modulate the FM signal generator with standard audio test modulation and set it to the standard test frequency. With the signal generator adjusted for 1-mV output, adjust the receiver volume control for an audio output power of 500 mW. Do not readjust the volume control for the remainder of the measurement. Remove the modulation from the signal generator and measure the audio hum and noise output power. Calculate the ratio, in decibels, of the audio output power to the hum and noise output power. This is the value for audio hum and noise (unscelched).

Set the squelch control to its maximum squelch position. Set the output level of the generator to zero and measure the audio hum and noise output power. Calculate the ratio, in decibels, of the audio output power to the hum and noise output power. This is the value for audio hum and noise (scelched).

5.7 Receiver Environmental Temperature Test

Place the receiver, with the power turned off, in the environmental chamber. Adjust the chamber to the required low temperature $\pm 2^\circ\text{C}$ ($\pm 3.6^\circ\text{F}$). Allow the receiver to reach temperature equilibrium as indicated by the internal thermometer, and maintain it at this temperature for 30 min. With the receiver still in the chamber, connect it to the standard supply voltage. Fifteen minutes after turn-on, test the receiver to determine whether it meets the requirements of section 4.7, following the procedures of sections 5.3 through 5.6. Return the receiver to room temperature and repeat the above procedure at the required high temperature $\pm 2^\circ\text{C}$ ($\pm 3.6^\circ\text{F}$).

5.8 Receiver Memory Retention Tests

5.8.1 Memory Retention Test for Loss of RF Signal

Connect the receiver and test equipment as shown in figure 2 and set the squelch control to the maximum unscelched position. Adjust the FM signal generator to the standard test frequency and set it for 1-mV output. Observe the receiver output. Decrease the generator signal to minimum output and disconnect the generator from the receiver. Reconnect the generator to the receiver and set its output to 1 mV. The receiver meets the requirement if it does not change frequency and indicates the correct rf signal from the generator.

5.8.2 Memory Retention Test for Loss of Power Supply

Connect the receiver and test equipment as shown in figure 2 and set the squelch control to the maximum unscelched position. Adjust the FM signal generator to the standard test frequency and set it for 1-mV output. Observe the receiver output. Disconnect the supply voltage, either ac or dc, from the receiver. Reconnect the supply voltage to the receiver. The receiver meets the requirement if it does not change frequency and indicates the correct rf signal from the generator.

5.9 Recorder Tests

Visually inspect the cassette recorder, cassette, and tape to insure that the requirements of sections 4.9.1 and 4.9.2 are met.

5.9.1 Fast Forward and Rewind Tests

Load a 30-min cassette tape in the tape recorder, set it to fast forward, and measure the time required to run the entire tape through the recorder in the fast-forward mode. Reset the recorder to rewind and measure the time required to run the entire tape through the machine in the rewind mode.

5.9.2 Tape Speed Test

Measure the diameter of the spindle of the tape recorder to ± 0.005 in using a micrometer or similar device. Connect the stroboscope accessory to the tape recorder capstan. Load the cassette tape in the recorder, place it in the record mode, and run for 1 h. Using a stroboscope with an accuracy of 1 percent or better, measure the speed of the capstan during the first 10 min. Calculate the tape speed using the equation

$$S = \frac{\pi dr}{60}$$

where π is the ratio needed to convert the spindle diameter to circumference, d is the spindle diameter in inches, r is the average capstan angular velocity in revolutions per min over the 10-min period, and S becomes the tape speed in inches per second.

Repeat the calculation using a capstan angular velocity measured during the last 10 min of the test period.

5.9.3 Anti-Erase Feature Test

Load a cassette tape in the tape recorder and record a typical segment of speech. Rewind the tape to its starting point, remove the cassette and activate the anti-erase mechanism. Replace the cassette in the recorder and attempt to place the recorder in the record mode.

5.10 Receiver/Recorder System Tests

When a receiver is connected to a recorder, proper shielding should be utilized and the manufacturer's instructions regarding capacitive coupling between the audio and remote control circuits should be followed.

5.10.1 System Audio Distortion Test

Connect the receiver, tape recorder, and test equipment as shown in figure 8. Modulate the FM generator with standard audio test modulation and set it to the standard test frequency. Record the signal using the tape recorder. Upon completion of 3 min of standard audio test modulation, rewind the recorded

cassette and play the recorded signal into the distortion analyzer at a suitable audio input level as observed on the visual audio indicator of the recorder. Measure the audio distortion.

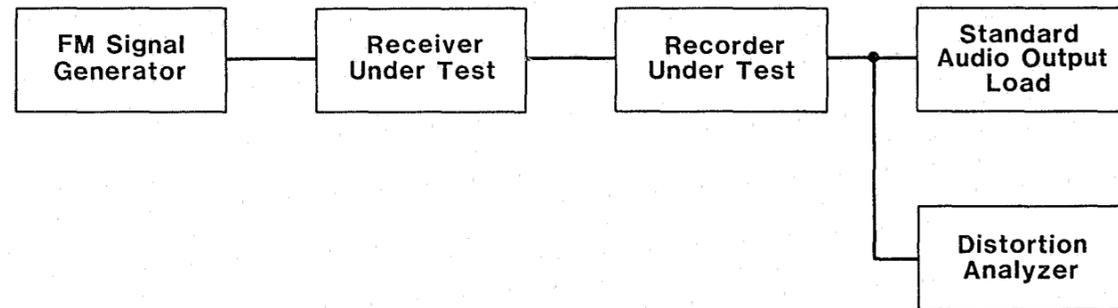

FIGURE 8. Block diagram for system audio distortion measurement.

5.10.2 System Audio Response Test

Connect the receiver, tape recorder, and test equipment as shown in figure 9. Set the FM signal generator to the standard test frequency and modulate it with standard audio test modulation with the generator output adjusted to 1 mV. Reduce the generator frequency deviation to 1 kHz and record 3 min of standard audio test modulation on the recorder. Do not make any adjustment, except on the FM signal generator, for the remainder of the measurement. Repeat the measurement using modulating frequencies of 0.3, 0.5, 1.5, 2.0, 2.5, and 3.0 kHz. Rewind the recorded tape and replay the tape, measuring the audio output power at each of the modulating frequencies. Compute the ratio, expressed in decibels, of each of these latter voltage levels to the voltage level at 1 kHz.

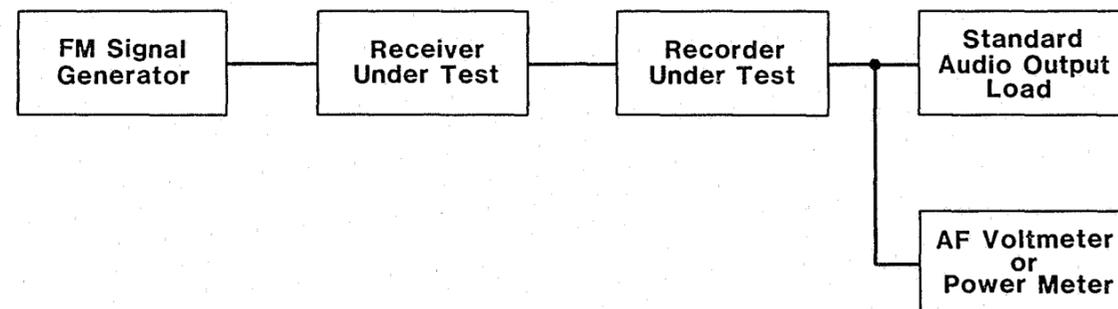

FIGURE 9. Block diagram for system audio response measurement.

5.10.3 Battery Service Life Test

Connect the receiver, tape recorder, and test equipment as shown in figure 10. Install a fully-charged set of batteries and load a new C 120 cassette tape in the recorder. If the receiver is not ac powered, install a fully-charged set of batteries in the receiver. Place the receiver in the unsquelched mode with the audio output power adjusted to a level suitable for recording as indicated by the recorder. Place the recorder in the record mode and note the starting time. Record for 4 h, replacing with a new cassette at the end of each hour. Remove the cassette tape and conduct the system audio distortion test (sec. 5.10.1) using a new cassette tape to insure that the system audio distortion is 15 percent or less.
